# OPTICAL ANALYSIS OF THE SYNCHROTRON RADIATION MONITORS IN DAФNE 

A. Ghigo, R. Huang, F. Sannibale

## Introduction

The radiation range that will be used in DAФNE synchrotron light monitors has been suggested to be $400 \div 600 \mathrm{~nm}$ [1]. In order to minimize the chromatic aberration two achromats will be used to image the electron and positron beams onto the photocathodes of detectors. By using achromats other kinds of aberrations will also be much smaller. Unfortunately, every achromat has some residual chromatic aberration that must be analysed in order to get a diffraction limited measurement of the beam size. Given the commercially available achromats such analysis will be done in this paper and the result shows that it is possible to set up an optical system with achromats to keep the aberration error smaller than the errors of beam itself, the diffraction limit error and the depth of field error[1]. Other related issues will also be discussed in this paper.

This note includes: 1 - Chromatic aberration and its connection with the beam curvature error and depth of field error; 2 - Geometric aberrations; 3-Quality of mirrors; 4-Size of the tilted mirror and of the second lens; 5 - Discussion of a possible phenomena during the detector position tuning.

## 1. Chromatic Aberration

### 1.1. The aberration of the two-achromat system

Figure 1-Schematic drawing of the synchrotron monitor optical system.

A typical two-achromat system is shown in Fig. 1, where $F_{1}$ and $F_{2}$ represent two achromats. The physical meanings of all the symbols in Fig. 1 are:

| $\mathrm{H}_{1}$ | Transverse beam dimension in storage ring. <br> $\mathrm{H}_{2}$ |
| :--- | :--- |
| $\mathrm{H}_{2}^{\prime}$ | Image of $\mathrm{H}_{1}$ without chromatic aberration. |
| Image of $\mathrm{H}_{1}$ at a specific wavelength with chromatic focal length shifts on both |  |
| lenses. |  |

Because of the separation between $\mathrm{H}_{2}$ and $\mathrm{H}^{\prime}$, a point beam source will have an image spot on the vertical plane at $\mathrm{H}_{2}$ position, with the vertical aberration parameters:
$\Delta_{2} \quad$ Half width of the spot.
$\Delta_{1} \quad$ Spot center deviation to the ideal image point, or the average image point.
The formulas of $\Delta_{1}$ and $\Delta_{2}$ for such system are given in Appendix A. With a set of commercially available data of $\mathrm{F}_{1}$ and $\mathrm{F}_{2}$ [2]: $\mathrm{L}_{1}=2254.18 \mathrm{~mm}, \mathrm{~L}_{2}=1250.70 \mathrm{~mm}$, $\delta_{1}=1.17 \mathrm{~mm}$, and $\delta_{2}=0.61 \mathrm{~mm}$ for wavelength from 488 nm to 633 nm , we get the aberration parameters in Table 1. Other parameters used for the calculation of Table 1 are: $\mathrm{L}=(25000-\mathrm{P})$ $\mathrm{mm}, \mathrm{a}=2 \mathrm{~mm}, \psi_{\text {typ }}=0.00468$ rad, beam vertical size $\mathrm{H}_{1 \mathrm{v}}=0.28 \mathrm{~mm}$, horizontal size $\mathrm{H}_{1 \mathrm{~h}}=$ 2.529 mm . In Table 1, the spot center relative shift is valid for both the vertical and horizontal images, i.e., $\Delta_{1 h} / \mathrm{H}_{2 h}=\Delta_{1 \mathrm{v}} / \mathrm{H}_{2 \mathrm{v}}=\Delta_{1} / \mathrm{H}_{2}$. From reference [1], the relative errors without image aberration are: vertical $\Delta Y=0.02901$, horizontal $\Delta X=0.007955$. The total relative errors in Table 1 are got with: $\Delta \mathrm{Y}_{\mathrm{t}}=\left[(1+\Delta \mathrm{Y})^{2}+\Sigma\left(\Delta_{\mathrm{V}} / \mathrm{H}_{\mathrm{V}}\right)^{2}\right]^{0.5}-1$ and $\Delta \mathrm{X}_{\mathrm{t}}=\left[(1+\Delta \mathrm{X})^{2}+\Sigma\left(\Delta_{\mathrm{h}} / \mathrm{H}_{\mathrm{h}}\right)^{2}\right] 0.5$ -1.
(i) Comparing the last two rows in the table with the original $\Delta \mathrm{Y}$ and $\Delta \mathrm{X}$, it can be seen that the image aberration has little influence on the total image relative errors. The total errors are still mainly determined by the parameters of the beam itself, the geometric errors and diffraction errors
(ii) In horizontal direction $\Delta_{1}$ is the dominant chromatic error and in vertical plane $\Delta_{2}$ is the dominant term.
(iii) The biggest relative error caused by chromatic aberration is the vertical relative spot size $\Delta_{2 v} / H_{2 v}$.

Here we suppose that the detector is put on one end of the longitudinal aberration spot. If we tune the detector to the middle of the spot, the relative aberration error in Table 1 will be half.

Table 1. Typical parameters for the two-lens system (unit: mm)

| Parameters | $\mathrm{P}=-100 \mathrm{~mm}$ | $\mathrm{P}=-50 \mathrm{~mm}$ | $\mathrm{P}=-20 \mathrm{~mm}$ | $\mathrm{P}=-10 \mathrm{~mm}$ | $\mathrm{P}=0 \mathrm{~mm}$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Longitudinal deviation $\Delta_{\mathrm{L}}$ | 0.7932 | 0.8569 | 0.9163 | 0.9415 | 0.9702 |
| Spot center shift $\Delta_{1} / \mathrm{H}_{2}$ | 0.01485 | 0.01223 | 0.01073 | 0.01024 | 0.009749 |
| Horizontal spot size $\Delta_{2 \mathrm{~h}} / \mathrm{H}_{2 \mathrm{~h}}$ | 0.001920 | 0.001466 | 0.001239 | 0.001170 | 0.001105 |
| Vertical spot size $\Delta_{2 \mathrm{v}} / \mathrm{H}_{2 \mathrm{v}}$ | 0.08756 | 0.06834 | 0.05853 | 0.05554 | 0.05268 |
| Magnification $\mathrm{H}_{2} / \mathrm{H}_{1}\left(\beta_{0}\right)$ | 0.3894 | 0.4578 | 0.5115 | 0.5323 | 0.5548 |
| Image position $\mathrm{X}_{2}\left(\Delta_{\mathrm{L}}=0\right)$ | 1272.30 | 1263.40 | 1256.38 | 1253.65 | 1250.70 |
| Total relative error-horizontal | 0.00807 | 0.00803 | 0.00801 | 0.00801 | 0.00800 |
| Total relative error-vertical | 0.03283 | 0.03135 | 0.03073 | 0.03056 | 0.03040 |

| $\mathrm{p}=0 \mathrm{~mm}$ | $\mathrm{p}=10 \mathrm{~mm}$ | $\mathrm{p}=20 \mathrm{~mm}$ | $\mathrm{p}=50 \mathrm{~mm}$ | $\mathrm{p}=100 \mathrm{~mm}$ | Parameters |

### 1.2. The connection with curvature and depth of field errors

Such connection between the chromatic errors and the geometric errors are analysed in Appendix B. The result is:
in horizontal plane:

$$
\begin{align*}
& \Delta_{1} / H_{2 h}=\frac{a}{H_{1 h}+a} \frac{\Delta_{L}\left(\delta_{1}=0\right)}{Z} \frac{2 L L_{1}}{L_{1}^{2}-P\left(L-L_{1}\right)}\left(\Delta X_{C} / H_{1 h}\right) \\
& \approx \frac{\Delta_{L}\left(\delta_{1}=0\right)}{Z} \frac{L L_{1}}{L_{1}^{2}-P\left(L-L_{1}\right)}\left(\Delta X_{C} / H_{1 h}\right), \quad \text { when } \mathrm{a} \approx \mathrm{H}_{1 \mathrm{~h}} \tag{1.1}
\end{align*}
$$

in vertical plane:

$$
\begin{equation*}
\frac{\Delta_{2 V}}{H_{2 V}}=\frac{\Delta_{L}}{Z} \frac{\Delta X_{D F}}{H_{1 V}} \tag{1.2}
\end{equation*}
$$

where the beam image length $Z^{\prime}=Z \beta_{0}{ }^{2}$ and in our system $Z=9.299 \mathrm{~mm}[1] ; \Delta X_{c}$ is beam curvature error and $\Delta X_{D F}$ is depth of field error.

We know form Table 1 that the biggest relative chromatic error is $\Delta_{2 v} / H_{2 v}$, and from eq. (1.2) we know that if chromatic longitudinal spot size $\Delta_{\mathrm{L}}<Z^{\prime}$ this chromatic error should be smaller than the depth of field error. The smaller the $\Delta_{\mathrm{L}}$, the smaller the chromatic transverse errors. This also enables us to make a judgment if chromatic aberration will be serious or not just from the size of $\Delta_{\mathrm{L}}$.

Table 2. Comparison between the spot longitudinal size and the image length

| Parameters | $\mathrm{P}=-100 \mathrm{~mm}$ | $\mathrm{P}=-50 \mathrm{~mm}$ | $\mathrm{P}=-20 \mathrm{~mm}$ | $\mathrm{P}=-10 \mathrm{~mm}$ | $\mathrm{P}=0 \mathrm{~mm}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\Delta_{\mathrm{L}}\left(\delta_{1}=0\right)$ | 0.6313 | 0.6225 | 0.6155 | 0.6129 | 0.6100 |
| $\Delta_{\mathrm{L}}$ | 0.7932 | 0.8569 | 0.9163 | 0.9415 | 0.9702 |
| Beam image length $\mathrm{Z}^{\prime}$ | 1.40975 | 1.94876 | 2.43310 | 2.63489 | 2.86263 |
| $\Delta_{\mathrm{L}} / Z^{\prime}$ | 0.5627 | 0.4397 | 0.3766 | 0.3573 | 0.3389 |
| $\frac{\Delta_{L}\left(\delta_{1}=0\right) L L_{1}}{Z^{\prime}\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]}$ | 3.4258 | 2.8934 | 2.5750 | 2.4691 | 2.3633 |

| $\mathrm{P}=0 \mathrm{~mm}$ | $\mathrm{P}=10 \mathrm{~mm}$ | $\mathrm{P}=20 \mathrm{~mm}$ | $\mathrm{P}=50 \mathrm{~mm}$ | $\mathrm{P}=100 \mathrm{~mm}$ | parameters |
| :--- | :---: | :---: | :---: | :---: | :--- |
| 0.6100 | 0.6069 | 0.6035 | 0.5911 | 0.5592 | $\Delta_{\mathrm{L}}\left(\delta_{1}=0\right)$ |
| 0.9702 | 1.0030 | 1.0409 | 1.1957 | 1.7313 | $\Delta_{\mathrm{L}}$ |
| 2.86263 | 3.12098 | 3.41565 | 4.59867 | 8.54061 | beam image length $\mathrm{Z}^{\prime}$ |
| 0.3389 | 0.3214 | 0.3047 | 0.2600 | 0.2027 | $\Delta_{\mathrm{L}} / Z^{\prime}$ |
| 2.3633 | 2.2575 | 2.1519 | 1.8355 | 1.3100 | $\frac{\Delta_{L}\left(\delta_{1}=0\right) L L_{1}}{Z\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]}$ |

$\Delta_{\mathrm{L}}(\delta=0), \Delta_{\mathrm{L}}, \Delta_{\mathrm{L}} / \mathrm{Z}^{\prime}$ and $\left[\Delta_{\mathrm{L}}\left(\delta_{1}=0\right) / \mathrm{Z}^{\prime}\right]\left\{\mathrm{LL}_{1} /\left[\mathrm{L}_{1}{ }^{2}-\mathrm{P}\left(\mathrm{L}^{\left.\left.\left.-\mathrm{L}_{1}\right)\right]\right\}}\right.\right.\right.$ are listed in Table 2. It can be seen that in our system, in vertical direction, the chromatic error should be several times smaller than the depth of field error because of the small value of $\Delta_{\mathrm{L}} / Z^{\prime}$; and in horizontal direction, the chromatic error will be $\sim 1.5$ to 3.5 times as much as the curvature error whose contribution to the total error however is very small [1]. That explains again that the chromatic error of such system should be very small.

### 1.3. Magnification flexible

From Table 1 we know that we may increase or decrease the image magnification by increasing or decreasing $P$.

The relative aberrations decease as the magnification increases (see Table 1) because of the decrease of $\Delta_{\mathrm{L}} / Z^{\prime}$ and $\Delta_{\mathrm{L}}(\delta=0) / Z^{\prime}$. However the photon flux per unit image area (or per photocathode pix) will also decrease as $\left|\beta_{0}\right|$ increases: flux $/ \mathrm{pix} \propto \beta^{-2}(\mathrm{~L}+\mathrm{P})^{-1}$.

Once the positions of the two lenses is fixed, the magnification of the system can be experimentally measured. The magnification can also be calculated if two of the three parameters are precisely measured: $\mathrm{P}, \mathrm{L}$ and $\mathrm{X}^{\prime}{ }_{20}$.

Using equation (A.11) and the two other $\beta_{0}$ expressions (A.11a, A.11b), the possible calculation errors could respectively be:

$$
\begin{gather*}
\frac{\Delta \beta_{0}}{\beta_{0}}=\left(1+\beta_{0} \frac{2 L_{1}+P}{L_{2}}\right) \frac{\Delta L_{1}}{L_{1}}+\left(1+\beta_{0} \frac{P}{L_{1}}\right) \frac{\Delta L_{2}}{L_{2}}-\frac{\beta_{0}}{L_{1} L_{2}}\left[\left(L-L_{1}-L_{2}\right) \Delta P+P \Delta L\right]  \tag{1.3}\\
\frac{\Delta \beta_{0}}{\beta_{0}}=\left\{\left[L\left(L_{2}-X_{20}^{\prime}\right)+X_{20}^{\prime} L_{2}\right] \frac{\Delta L_{1}}{L_{1}}-X_{20}^{\prime}\left(L-L_{1}\right) \frac{\Delta L_{2}}{L_{2}}-\left(L_{2}-X_{20}^{\prime}\right) \Delta L+\left(L-L_{1}-L_{2}\right) \Delta X_{20}^{\prime}\right\} \times \\
\frac{1}{L_{1} L_{2} \beta_{0}} \tag{1.4}
\end{gather*}
$$

and

$$
\begin{equation*}
\frac{\Delta \beta_{0}}{\beta_{0}}=\frac{\Delta L_{1}}{L_{1}}+\frac{X_{20}^{\prime}}{L_{2}-X_{20}^{\prime}} \frac{\Delta L_{2}}{L_{2}}-\frac{\Delta X_{20}^{\prime}}{L_{2}-X_{20}^{\prime}}-\frac{\Delta P}{P} \tag{1.5}
\end{equation*}
$$

The manufacturing tolerance of focal length could be $1 \%$ [2]. If we suppose the distance measurement errors be: $\Delta \mathrm{L}=10 \mathrm{~mm}, \Delta \mathrm{P}=5 \mathrm{~mm}$ and $\Delta \mathrm{X}^{\prime}{ }_{20}=1 \mathrm{~mm}$, the r.m.s from all the terms in each equation will be:

| $\beta_{\mathrm{o}}$ | $-0.3894(\mathrm{P}=-100 \mathrm{~mm})$ | $-0.5548(\mathrm{P}=0 \mathrm{~mm})$ | $-0.9584(\mathrm{P}=100 \mathrm{~mm})$ |  |
| :---: | :---: | :---: | :---: | :---: |
|  | 0.0184 | 0.0254 | 0.0455 |  |
| $\left\|\Delta \beta / \beta_{\mathrm{o}}\right\|$ | 0.2645 | 0.1827 | 0.1017 | eq.(1.4) |
|  | 0.5930 | infinite | 0.2317 | eq.(1.5) |

It seems possible for us to calculate the magnification with a precision $\sim 2-5 \%$, depending on P , L or $\mathrm{X}^{\prime}{ }_{20}$ measurement precision, with eq.(A.11).

## 2. Geometric Aberrations

Geometric aberrations have been classified with different names and their vertical aberration sizes have different relations with optic ray parameters: spherical aberration, $\propto r^{3}$; coma, $\propto r^{2} h$; astigmatism and field curvature, $\propto \mathrm{rh}^{2}$; and distortion, $\propto \mathrm{h}^{3}$, where r is the aperture size and h is the image vertical size, the off axis distance[3]. Normally, the optical manufacturing companies design the achromats in such a way to let the Abbe sine conditions be almost satisfied. Therefore both the spherical aberration and coma are very small when the wavelength is close to the design one (page A24 of [2]; page 5-2 of [4]; page B-76 of [5]).

The Modulation Transfer Function (MTF) is normally used experimentally to describe the image quality of an optical system [4]. MTF curves describe the ability of a lens or system, as a function of spatial frequency, to transfer object contrast to the image. For a spatially modulated source with intensities $\mathrm{T}_{\max }$ and $\mathrm{T}_{\min }$, if the image has the intensities $\mathrm{I}_{\max }$ and $\mathrm{I}_{\min }$, at a given spatial frequency, the MTF will be:

$$
M T F=\frac{\left(I_{M A X}-I_{M I N}\right) /\left(I_{M A X}+I_{M I N}\right)}{\left(T_{M A X}-T_{M I N}\right) /\left(T_{M A X}+T_{M I N}\right)}
$$

The MTF can describe the total effects of all kinds of aberrations. In our system, if we want all other aberrations smaller than the chromatic errors, for example in the vertical direction, $\Delta_{2 \mathrm{v}}$ $\approx \mathrm{h}_{1 \mathrm{v}} \beta\left(\Delta_{2 \mathrm{v}} / \mathrm{h}_{2 \mathrm{v}}\right) \approx 0.28^{*} 0.5^{*} 0.05 \approx 0.007 \mathrm{~mm}$, we need a satisfied MTF for spatial frequency up to 140 cycle $/ \mathrm{mm}$. The MTF data also depends on the lens focal ratio. For the second lens of our system, the vertical illuminated area will be $\mathrm{d}=2\left(\mathrm{~T}+\mathrm{t}^{\prime}\right) \approx 45 \mathrm{~mm}$, the effective focal ratio will be $\mathrm{f} / \mathrm{d}=1250 / 45 \approx 28$.

On page 5-4 of reference[4], a typical on-axis MTF curve of an achromat with $\mathrm{f} / \mathrm{d}=3.77$, which is $\sim 1 / 7$ of the vertical effective focal ratio of our system, has been given. That figure shows that at the spatial frequency of 140 the MTF will be 0.27 . Considering the spherical aberration being proportional to $\mathrm{r}^{3}$, or $\mathrm{d}^{3}$, we can believe that the on-axis spherical aberration of our system with such kind of achromats will be very small and negligible.

However, for the off-axis image, which may be caused by the size of the source or misalignment, the astigmatism aberration will be introduced. In the figure of page 5-6 of reference [4] it has been shown that with a field angle of $2.5^{\circ}$, when spatial frequency is 14 cycle $/ \mathrm{mm}$, the MTF will decrease to 0.2 (The Rayleigh range of a perfect system corresponding to MTF $=0.22$ ). Because the astigmatism is proportional to $\mathrm{rh}^{2}$, the spatial resolution of the second lens in our system might be $\sim 7$ times better than 14 cycle $/ \mathrm{mm}$, that is only 100 cycle $/ \mathrm{mm}$ at the $2.5^{\circ}$ field angle. On the other hand, because the astigmatism is proportional to the square of field angle, we can get a better spatial resolution by keeping a smaller field angle. So, roughly, less than $2^{\circ}$ is basically required for our system.

In conclusion, if the achromats have similar quality to those described in reference [4], the spherical aberration and coma could be very small and negligible and the astigmatism could also be small enough when we keep the field angle, roughly saying, smaller than $2^{\circ}$. The field angle caused by beam transverse size is very small and negligible; We just need to pay attention to alignment in order to keep a small field angle.

## 3. The Quality of Mirrors

The following is only a rough discussion about this issue.

Figure 2 - Position of the five mirrors
Five mirrors will possibly be used in the optical system: two before the first lens and three others between the two lenses, as shown in Fig. 2. Some company describes the mirror surface error with "spherical error" and "irregular error", which represent the spherical deviation and irregular deviation from an ideal surface respectively [5].

For simplicity, we treat defect mirror surface as an average spherical shallow (or convex) one, as shown in Fig. 3(b), and we assume that such spherical surface influence on image will not be so perfect that can be compensated just by finely tuning the position of detector, therefore it will be an effect of image distortion.

Figure 3 - Image distortion by a defected mirror

Figure 3(a) shows a bunch of light coming from a point source and having a radiation angle of $\theta_{1}$. the source distance to the mirror is $x$. The two rays, separated by a distance $w_{1}$, reflected at two different points, which form an angle $\beta$ on the distorted mirror change the radiation angle into $\quad \theta_{2} . \quad$ In Fig. $3(\mathrm{a}), \quad \angle \mathrm{IEB}=\gamma, \quad \angle \mathrm{GAD}=\alpha, \quad \angle \mathrm{EBD}=\beta, \quad \angle \mathrm{IDB}=\alpha-\theta_{1}$; $\angle \mathrm{IEB}=\angle \mathrm{EBD}+\angle \mathrm{IDB}=\beta+\alpha-\theta_{1}$, i.e. $\gamma=\beta+\alpha-\theta_{1}$. On the other hand, $\angle \mathrm{OCD}=\alpha-\theta_{2}$ and $\angle \mathrm{OCD}=\angle \mathrm{EBD}+\angle \mathrm{BEC}=\beta+\gamma$, therefore, $\theta_{2}=\alpha-\beta-\gamma=\theta_{1}-2 \beta$.

Because $\mathrm{x} \approx \mathrm{w}_{1} / \theta_{1}, \mathrm{x}^{\prime} \approx \mathrm{w}_{2} / \theta_{2}, \angle \mathrm{EAF}=\angle \mathrm{BAF}+\beta / 2=\alpha+\beta / 2$,

$$
\begin{equation*}
\mathrm{w}_{1}=\overline{A E} \sin \angle \mathrm{EAF}=\mathrm{d} \sin (\alpha+\beta / 2) \tag{3.1}
\end{equation*}
$$

Similarly,

$$
\begin{equation*}
\mathrm{w}_{2}=\mathrm{d} \sin (\alpha-\beta / 2) \approx \mathrm{w}_{1}-\beta \mathrm{d} \cos \alpha \tag{3.2}
\end{equation*}
$$

because of $\beta \ll \alpha$, the longitudinal position distortion caused by the mirror will be:

$$
\begin{equation*}
\Delta x=x^{\prime}-x=\frac{w_{2}}{\theta_{2}}-\frac{w_{1}}{\theta_{1}}=\frac{w_{1}\left(\theta_{1}-\theta_{2}\right)-\theta_{1} \beta d \cos \alpha}{\theta_{1} \theta_{2}}=\frac{2 w_{1} \beta-\theta_{1} \beta d \cos \alpha}{\theta_{1} \theta_{2}} \tag{3.3}
\end{equation*}
$$

for $\Delta x \ll x^{\prime}$ and $x$, then $\theta_{2}-\theta_{1} \ll \theta_{1}, \theta_{2}$,

$$
\begin{equation*}
\Delta x=\frac{2 x^{2} w_{1} \beta-w_{1} x \beta d \cos \alpha}{w_{1}^{2}} \approx 2 \beta \frac{x^{2}}{d}\left(\frac{1}{\sin \alpha}-\frac{d \cos \alpha}{2 x \sin \alpha}\right) \tag{3.4}
\end{equation*}
$$

On the other hand, from Fig. 3(b), there is the relationship,

$$
\begin{equation*}
h=\frac{d}{2}\left[\frac{1}{\sin \beta / 2}-\frac{1}{\operatorname{tg} \beta / 2}\right]=\frac{d}{2} \frac{1-\cos \beta / 2}{\sin \beta / 2}=\frac{d}{2} \frac{(\beta / 2)^{2} / 2\left(1-\frac{(\beta / 2)^{2}}{12}+\ldots\right)}{(\beta / 2)\left(1-\frac{(\beta / 2)^{2}}{6}+\ldots\right)} \approx \frac{d}{8} \beta \tag{3.5}
\end{equation*}
$$

From (3.4) and (3.5):

$$
\begin{equation*}
h=\frac{1}{16}\left(\frac{d}{x}\right)^{2} \Delta x\left(\frac{1}{\sin \alpha}-\frac{d \cos \alpha}{2 x \sin \alpha}\right)^{-1} \approx \frac{\sin \alpha}{16}\left(\frac{d}{x}\right)^{2} \Delta x \tag{3.6}
\end{equation*}
$$

For M2, for example, if we suppose $\mathrm{d} / \mathrm{x}=50 / 1623 \mathrm{~mm}$ and $\sin \alpha=\sin 45^{\circ}, \Delta \mathrm{x}=1.17 \mathrm{~mm}$, the value of the chromatic focus shift of $\mathrm{F}_{1}$, than we get $\mathrm{h}=0.0000491 \mathrm{~mm}=\lambda / 12$, where $\lambda=6000 \AA$; If we choose $\Delta x=4.65 \mathrm{~mm}$, half source length, we will get $\mathrm{h}=0.000195 \mathrm{~mm} \approx$ $\lambda / 3$.

If we treat the defected mirror with the paraxial Gauss Optics formulas for a simple estimation, the focus of the mirror is:

$$
f=-\frac{r}{2} \approx-\frac{d^{2}}{16 h}
$$

then,

$$
\Delta x=\left|x^{\prime}\right|-|x|=\left|\frac{f x}{f+x}\right|-x=-\frac{x^{2}}{f+x} \approx-\frac{x^{2}}{f}=\frac{16 x^{2}}{d^{2}} h, \text { if }|f| \gg x,
$$

and,

$$
\begin{equation*}
h=\frac{1}{16}\left(\frac{d}{x}\right)^{2} \Delta x \tag{3.7}
\end{equation*}
$$

Eq. (3.7) is the same as (3.6) when $\alpha=90^{\circ}$.
Similarly, we discussed the quality requirement for the mirrors between the two lenses in Appendix C, which give us the suggested $\lambda$ flatness.

Regarding for the irregular error of a mirror, the distortion on the image could be more serious. For example, if an irregular defect happens with a dimension of $d / 3$, the limit of irregular depth " $h$ " should be about one order smaller than the regular one because of $h \propto d^{2}$. The image of the beam may be more seriously influenced from the irregular surface error considering the following parameters: the size of the horizontal spot on the mirrors from a point source will only be several millimeters, the size of the slit, and the total vertical dimension of the spot on mirrors from the whole beam will be $\sim 30 \div 40$ millimeters. Unfortunately, we can not give an explicit limit for the irregular defect. However from the discussion above we know that the mirror flatness should at least better than the order of $\lambda$ because of regular "spherical error". Perhaps better than $\lambda / 10$ might be a basic requirement for the general flatness.

## 4. Mirror Size and the Second Lens Size

## 1. Size of the tilted mirror

We only discuss the size of $\mathrm{M}_{3}$, because the incident angle on this mirror is large and therefore the size of mirror is large.

Figure 4 - The size of $\mathrm{M}_{3}$ mirror.

Horizontally, in Fig. 4(a), $\mathrm{t}=\mathrm{a}$, the slit size, $\mathrm{H}_{1}=2 \delta_{\mathrm{x}}$. The width of the mirror will be $\mathrm{W}=2\left(\mathrm{~T}+\mathrm{t}^{\prime}\right)$, referring to eq.(A.14) about $\mathrm{t}^{\prime}$, there will be:

$$
\begin{equation*}
W=2 H=2\left[\frac{S}{L_{1}+P} H_{1}+a \frac{L_{1}^{2}-P\left(S-L_{1}\right)}{L_{1}\left(L_{1}+P\right)}\right]=42.6 \mathrm{~mm} \tag{4.1}
\end{equation*}
$$

Vertically, we take $\mathrm{t}=1.5 \psi_{\text {typ }}\left(\mathrm{L}_{1}+\mathrm{P}\right)$, for in Fig. 2 of Ref.[6] the synchrotron light will apparently exist till $\psi=1.5 \psi_{\text {typ }}$ when $\varepsilon / \varepsilon_{c}=\lambda_{\mathrm{c}} / \lambda=0.01$. (In DAФNE, $\lambda_{\mathrm{c}}=62 \mathrm{~A}$, and the light used in the monitor $\lambda=500 \AA$ ). $\mathrm{H}_{1}=2 \delta_{\mathrm{y}}$.

$$
\begin{gather*}
H_{T}=2 H=2\left[\frac{S}{L_{1}+P}\left(2 \delta_{Y}\right)+t \frac{L_{1}^{2}-P\left(S-L_{1}\right)}{L_{1}\left(L_{1}+P\right)}\right] \\
L=H_{T} / \sin \alpha=2\left[\frac{S}{L_{1}+P}\left(2 \delta_{Y}\right)+1.5 \psi_{t y p}\left(L_{1}+P\right) \frac{L_{1}^{2}-P\left(S-L_{1}\right)}{L_{1}\left(L_{1}+P\right)}\right] / \sin \alpha=235 \mathrm{~mm} \tag{4.2}
\end{gather*}
$$

Other data used in the calculation are: $\mathrm{L}_{1}=2250 \mathrm{~mm}, \mathrm{P}=0, \mathrm{~S}=8127 \mathrm{~mm}, \mathrm{a}=3 \mathrm{~mm}$, $\delta_{\mathrm{x}}=2.53 \mathrm{~mm}, \delta_{\mathrm{y}}=0.28 \mathrm{~mm}, \psi_{\mathrm{typ}}=0.467 \mathrm{E}-2 \mathrm{rad}, \alpha=17.43^{\circ} / 2=8.715^{\circ}$. The result shows that the mirror could not be smaller than $42.6 * 235 \mathrm{~mm}$. The minimum size of the mirror will be changed by the change of the beam parameters. We list the required mirror dimension against the beam parameters as following:

Mirror size vs beam coupling ( $\mathrm{P}=0$, beam position: center)

| k | 0.01 | 0.05 | 0.1 | 0.2 | 0.4 |
| :--- | :--- | :---: | :---: | :---: | :---: |
| $\Delta \mathrm{~W}(\mathrm{~mm})$ | 0 | -0.7 | -1.5 | 3 | 5.5 |
| $\Delta \mathrm{~L}(\mathrm{~mm})$ | 0 | 31.7 | 54.0 | 82.5 | 116.3 |

Mirror size vs beam horizontal shift ( $\mathrm{P}=0$ )

| $\Delta \mathrm{X}(\mathrm{mm})$ | 1.0 | 2.0 | 5.0 | 10.0 | 20.0 |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $\Delta \mathrm{~W}(\mathrm{~mm})$ | 7.3 | 14.5 | 36.2 | 72.3 | 144.5 |

Mirror size vs beam vertical shift ( $\mathrm{P}=0$ )

| $\Delta \mathrm{Z}(\mathrm{mm})$ | 0.1 | 0.5 | 1.0 | 5.0 | 10.0 |
| :--- | :--- | :---: | :---: | :---: | :---: |
| $\Delta \mathrm{~L}(\mathrm{~mm})$ | 4.7 | 23.8 | 47.6 | 238.3 | 476.7 |

Mirror size vs beam longitudinal position (horizontal position: center)

| $\mathrm{P}(\mathrm{mm})$ | 100.0 | 20.0 | 0.0 | 20.0 | 100.0 |
| :--- | ---: | :---: | :---: | :---: | :---: |
| $\Delta \mathrm{~W}(\mathrm{~mm})$ | 2.6 | 0.6 | 0.0 | -0.6 | -2.6 |
| $\Delta \mathrm{~L}(\mathrm{~mm})$ | 25.3 | 5.0 | 0.0 | -5.0 | 25.3 |

The longitudinal position has little influence on the mirror size; We can increase M3 mirror size for possible larger beam coupling; We can remote control the longitudinal position of M2 to compensate beam vertical shift in order to limit the size of M3; By properly rotate M2 mirror, we can compensate beam horizontal shift. However, the rotation control should be a very precise one, for 0.1 degree rotation of M2 will be equal to 5.66 mm beam horizontal shift given the M2 being 1662.7 mm away from beam.

An alternative way to compensate the beam horizontal shift is to move the horizontal position of F1 lens and the horizontal slit simultaneously, as shown in Fig. 5. In this way the tangential point of the beam to the principal optical ray can keep unchanged. The increased field angle in this case could also be small. Move F1 vertically can also compensate beam vertical shift.

Figure 5 - Compensation of beam horizontal shift

Position control of M2 and F1 (or only F1) will be needed not only to limit the size of M3, but also to make sure that the image will not be cut by the second lens (see "the size of the second lens").

## 2. Size of the second lens

The distance between the lenses is $\mathrm{S}=\mathrm{L}=25000 \mathrm{~mm}$; the horizontal and vertical size requirement will be: $\mathrm{W}=118 \mathrm{~mm}$ and $\mathrm{H}_{\mathrm{T}}=44 \mathrm{~mm}$, when $\mathrm{P}=0$ and $\mathrm{t}=3 \mathrm{~mm}$. The diameter of the second lens should $\sim 118 \mathrm{~mm}$.

If we choose the $\mathrm{L}_{2}=1250 / \Phi=150 \mathrm{~mm}$ lens, then maximum beam width that can be measured will be $2.51 \delta_{\mathrm{x}}$ for $\mathrm{P}=0 \mathrm{~mm}$ and $\mathrm{t}=3 \mathrm{~mm}$.

Without position control of F1 or M2, with $\sim 6.5 \mathrm{~mm}$ beam transverse position shift, the beam image will be cut by the second lens up to beam center. The large transverse beam shift must be compensated properly in our optical system.

## 5. Discussion

In order to set the detector precisely on the image surface, we will probably have to tune the detector longitudinally till the image of the beam is very clear or the size of the beam reaches its minimum value. But it probably happens that the horizontal size and the vertical size of the beam will not reach their minimum values at the same position when the detector slides along the optical axis because the image position is not the horizontal minimum size position.

In Fig. 6, if the detector is located at $X_{2}{ }^{\prime \prime}$ instead of the right position of $X_{20}^{\prime}$, and if $b_{1}<b_{2}$, then the image size will be smaller than $\mathrm{H}_{2}$. On the other hand, if the image has a minimum size at image position, it needs the condition:

$$
\begin{equation*}
\psi^{\prime}>\psi_{2} . \tag{5.1}
\end{equation*}
$$

Figure 6 - The image with a longitudinal deviation

From Appendix B we know that,

$$
\begin{gathered}
\psi^{\prime}=\frac{t^{\prime}}{X_{20}^{\prime}}=\frac{t}{\left|\beta_{0}\right|\left(L_{1}+P\right)} \\
\psi_{2}=\frac{T-H_{2}}{X_{20}^{\prime}} \approx \frac{T-H_{Q^{\prime}}}{X_{20}^{\prime}}=T\left(\frac{1}{L_{2}}-\frac{1}{L}\right) \approx \frac{T}{L_{2}}=\frac{L}{L_{2}\left(L_{1}+P\right)} H_{1}
\end{gathered}
$$

then condition (5.1) means:

$$
\begin{equation*}
t>\left|\beta_{0}\right| \frac{L}{L_{2}} H_{1} \tag{5.2}
\end{equation*}
$$

or:

$$
\begin{equation*}
\psi=\left|\beta_{0}\right| \psi^{\prime}>\left|\beta_{0}\right| \frac{L}{L_{2}\left(L_{1}+P\right)} H_{1} \tag{5.3}
\end{equation*}
$$

t and $\psi$ are respectively the slit half width and the source divergence angle to the slit, $\mathrm{H}_{1}$ is the beam transverse size. The typical data for our system could be: $\mathrm{L}=25000 \mathrm{~mm}$, $\mathrm{L}_{2}=1250 \mathrm{~mm}, \mathrm{~L}_{1}=2250 \mathrm{~mm}$, and we may choose $\mathrm{P}=0$ and $\beta_{0}=0.5556$ for simplicity. In horizontal plane, $\mathrm{H}_{1}=2.529 \mathrm{~mm}$, eqs. (5.2) and (5.3) require: $\mathrm{t}>28.1 \mathrm{~mm}$ and $\psi>0.02248 \mathrm{rad}$ $=1.3^{\circ}$. In vertical plane, $\mathrm{H}_{1}=0.2792 \mathrm{~mm}$, they require: $\mathrm{t}>3.1 \mathrm{~mm}$ and $\psi>0.00248 \mathrm{rad}$. Because in our system, in horizontal direction, the slit will be $\sim 1 \mathrm{~mm}$ but in the vertical direction $\psi$ will be the divergence of the synchrotron light itself which is $\sim 0.004677 \mathrm{rad}$ [1], we can expect a vertical minimum size image at the perfect image position but can not expect the minimum horizontal one there.

In Fig. 6, we can approximately take $\mathrm{X}_{2}{ }^{\prime \prime}$ as the minimum size position of the horizontal image, then there is,

$$
\begin{equation*}
X_{2}^{\prime \prime}-X_{20}^{\prime} \approx \frac{H_{2}}{\psi_{2}} \approx \frac{H_{2}\left(L_{1}+P\right) L_{2}}{L H_{1}}=\left|\beta_{0}\right| \frac{\left(L_{1}+P\right) L_{2}}{L} \tag{5.4}
\end{equation*}
$$

and the minimum spot size:

$$
H^{\prime \prime}=\psi^{\prime}\left(X_{2}^{\prime \prime}-X_{20}^{\prime}\right) \approx \frac{L_{2}}{L} t
$$

For $\mathrm{P}=0, \mathrm{X}_{2}{ }^{\prime \prime}-\mathrm{X}_{2}{ }^{\prime}=40 \mathrm{~mm}$. That means that the minimum size positions for horizontal and vertical images can be separated by $\sim 40 \mathrm{~mm}$.

## Appendix A

## The Image and its Aberration

In following calculation, the distance of an image, or source, will be positive if it is located on the right side of a lens, and will be negative if on the left side. $\mathrm{X}^{\prime}$ is the image position of a source locating at X .

## A.1. Image positions

For the first lens in Fig. 1,

$$
\begin{gather*}
X_{1}=-\left(L_{1}+P\right)  \tag{A.1}\\
X_{1}^{\prime}=\frac{f_{1} X_{1}}{f_{1}+X_{1}} \tag{A.2}
\end{gather*}
$$

and for the second lens,

$$
\begin{gather*}
X_{2}=X_{1}^{\prime}-L  \tag{A.3}\\
X_{2}^{\prime}=\frac{f_{2} X_{2}}{f_{2}+X_{2}}=\frac{f_{2}\left[\left(L_{1}+P\right)\left(L-f_{1}\right)-f_{1} L\right]}{\left(L_{1}+P\right)\left(L-f_{1}-f_{2}\right)-f_{1}\left(L-f_{2}\right)} \tag{A.4}
\end{gather*}
$$

With $\mathrm{f}_{1}=\mathrm{L}_{1}+\delta_{1}, \mathrm{f}_{2}=\mathrm{L}_{2}+\delta_{2}$, we get:

$$
X_{2}^{\prime}=\frac{L_{2}\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]+L_{2}\left(L+L_{1}+P\right) \delta_{1}+\left[L_{1}^{2}-P\left(L-L_{1}\right)\right] \boldsymbol{\delta}_{2}}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)+\left(L+L_{1}-L_{2}+P\right) \delta_{1}+P \boldsymbol{\delta}_{2}}
$$

with the assumption:

$$
\begin{gather*}
\left(L+L_{1}-L_{2}+P\right) \delta_{1} \ll L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)  \tag{A.5}\\
P \delta_{2} \ll L_{1}^{2}-P\left(L-L_{1}-L_{2}\right) \tag{A.6}
\end{gather*}
$$

and keeping the first-order of $\delta_{1}, \delta_{2}$ during the expansion, we can get:

$$
\begin{equation*}
X_{2}^{\prime}=\frac{L_{2}\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)}+\left[\frac{L_{2}\left(L_{1}+P\right)}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)}\right]^{2} \delta_{1}+\left[\frac{L_{1}^{2}-P\left(L-L_{1}\right)}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)}\right]^{2} \delta_{2} \tag{A.7}
\end{equation*}
$$

Thus, the ideal image position without chromaticity is:

$$
\begin{equation*}
X_{20}^{\prime}=X_{2}^{\prime}\left(\delta_{1}, \delta_{2}=0\right)=\frac{L_{2}\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)} \tag{A.8}
\end{equation*}
$$

and the longitudinal spot size caused by the residual chromatic aberration of the two achromats:

$$
\begin{equation*}
\Delta_{L}=\left[\frac{L_{2}\left(L_{1}+P\right)}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)}\right]^{2} \delta_{1}+\left[\frac{L_{1}^{2}-P\left(L-L_{1}\right)}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)}\right]^{2} \delta_{2} \tag{A.9}
\end{equation*}
$$

## A.2. Magnification

The transverse magnification of the system, under the assumptions of eq.(A.5) and (A.6), will be:

$$
\begin{gathered}
\beta=\frac{X_{2}^{\prime} X_{1}^{\prime}}{X_{2} X_{1}}=\frac{f_{1} f_{2}}{\left(L_{1}+P\right)\left(L-f_{1}-f_{2}\right)+f_{1}\left(f_{2}-L\right)} \\
=-\frac{L_{1} L_{2}+L_{2} \delta_{1}+L_{1} \delta_{2}}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)+P \delta_{2}+\left(L-L_{2}+L_{1}+P\right) \delta_{1}} \\
\approx-\frac{L_{1} L_{2}}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)}+\frac{L_{1}\left(L-L_{2}\right)\left(L_{1}+P\right)}{\left[L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)\right]^{2}} \delta_{1}-\frac{L_{1}\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]}{\left[L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)\right]^{2}} \delta_{2}
\end{gathered}
$$

and,

$$
\begin{equation*}
\beta_{0}=\beta\left(\delta_{1}, \boldsymbol{\delta}_{2}=0\right)=-\frac{L_{1} L_{2}}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)} \tag{A.11}
\end{equation*}
$$

From eq.(A.8) we can get:

$$
P=\frac{L_{1}^{2}\left(L_{2}-X_{20}^{\prime}\right)}{L_{2}\left(L-L_{1}\right)-X_{20}^{\prime}\left(L-L_{1}-L_{2}\right)}
$$

and

$$
L-L_{1}-L_{2}=\frac{L_{1}^{2}\left(L_{2}-X_{20}^{\prime}\right)-L_{2}^{2} P}{P\left(L_{2}-X_{20}^{\prime}\right)},
$$

inserting these into eq.(A.11) gives:

$$
\begin{equation*}
\beta_{0}=-\frac{L_{2}\left(L-L_{1}\right)-X_{20}^{\prime}\left(L-L_{1}-L_{2}\right)}{L_{1} L_{2}} \tag{A.11a}
\end{equation*}
$$

and

$$
\begin{equation*}
\beta_{0}=-\frac{L_{1}\left(L_{2}-X_{20}^{\prime}\right)}{L_{2} P} \tag{A.11b}
\end{equation*}
$$

Theoretically, with any two of the three parameters: $\mathrm{P}, \mathrm{L}$ and $\mathrm{X}_{20}$, the magnification can be calculated.

## A.3. Transverse aberration size

The aberration spot center transverse shift shown in Fig. 1 will be:

$$
\Delta_{1}=\left|H_{2}\right|-\left|H_{2}^{\prime}\right|+\left(X_{20}^{\prime}-X_{2}^{\prime}\right) \frac{T-\left|H_{2}^{\prime}\right|}{\left|X_{2}^{\prime}\right|}
$$

where $\mathrm{H}_{2}=\beta_{0} \mathrm{H}_{1}, H_{2}^{\prime}=\beta \mathrm{H}_{1}$ and $\mathrm{T}=\mathrm{LH}_{1} /\left(\mathrm{L}_{1}+\mathrm{P}\right)$. With the further approximations: $\Delta_{\mathrm{L}} \ll \mathrm{X}_{2}^{\prime}$ and $\left|H_{2}-H_{2}^{\prime}\right| \ll\left|H_{2}\right|$, and keeping the first order of $\delta_{1}$ and $\delta_{2}$, it can be obtained:

$$
\begin{gathered}
\Delta_{1}=-\left(|\beta|-\left|\beta_{0}\right|\right) H_{1}-\Delta_{L} \frac{\frac{L}{P+L_{1}}-|\beta|}{X_{20}^{\prime}+\Delta_{L}} H_{1} \approx-\left(|\beta|-\left|\beta_{0}\right|\right) H_{1}-\Delta_{L} \frac{\frac{L}{P+L_{1}}-\left|\beta_{0}\right|}{X_{20}^{\prime}} \\
=-\frac{L\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]}{L_{2}\left(P+L_{1}\right)\left[L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)\right]} H_{1} \delta_{2}
\end{gathered}
$$

or,

$$
\begin{equation*}
\frac{\Delta_{1}}{H_{2}}=\frac{L\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]}{\left(P+L_{1}\right) L_{1} L_{2}^{2}} \delta_{2} \tag{A.12}
\end{equation*}
$$

or even,

$$
\begin{equation*}
\Delta_{1}=-\frac{T \Delta_{L}\left(\boldsymbol{\delta}_{1}=0, \boldsymbol{\delta}_{2} \neq 0\right)}{X_{20}^{\prime}} \tag{A.13}
\end{equation*}
$$

The physical meaning of $\Delta_{1}$ described by (A.13) is more clear, as shown in $\operatorname{Fig}(A .1): \Delta_{1}$ is just the two rays vertical separation because of the second lens chromatic longitudinal image shift. When $\mathrm{P}=0, \Delta_{\mathrm{L}}\left(\delta_{1}=0\right)=\delta_{2}$, just the focus shift of the second lens.

Figure A. 1 - The equivalent meaning of $\Delta_{1}$

On the other hand, with the assumptions $\delta_{1} \ll \mathrm{~L}_{1}, L \delta_{1} \ll L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)$ and $\Delta_{\mathrm{L}} \ll \mathrm{X}_{2}^{\prime}$,

$$
\begin{gather*}
\alpha=\frac{t}{X_{1}^{\prime}}=t\left(\frac{1}{f_{1}}+\frac{1}{X_{1}}\right) \approx t\left[\frac{P}{L_{1}\left(L_{1}+P\right)}-\frac{\delta_{1}}{L_{1}^{2}}\right] \\
t^{\prime}=t-\alpha L=\frac{L_{1}^{2}-P\left(L-L_{1}\right)}{L_{1}\left(L_{1}+P\right)} t+\frac{L \delta_{1}}{L_{1}^{2}} \tag{A.14}
\end{gather*}
$$

The aberration spot size will be:

$$
\begin{gather*}
\Delta_{2}=\frac{\Delta_{L}}{X_{2}^{\prime}} t^{\prime} \approx \frac{\Delta_{L}}{X_{20}^{\prime}} t^{\prime}\left(\delta_{1}=0\right) \\
=\left\{\frac{L_{2}\left(L_{1}+P\right)}{L_{1}\left(L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)\right)} \delta_{1}+\frac{\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]^{2}}{L_{1} L_{2}\left(L_{1}+P\right)\left[L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)\right]} \delta_{2}\right\} t \tag{A.15}
\end{gather*}
$$

Because $\Delta_{1}$ is proportional to the beam transverse dimension $\left(\mathrm{H}_{1}\right)$ and $\Delta_{2}$ is proportional to the illuminated size ( t ) on the first lens, the $\Delta_{1}$ error will be larger than D 2 in the horizontal plane and D 2 will be larger than D 1 in the vertical plane.

In vertical plane, because $t=\Psi\left(L_{1}=P\right), \Delta_{2}$ can also be written as:

$$
\begin{equation*}
\frac{\Delta_{2 V}}{H_{2 V}}=\left[\frac{\left(L_{1}+P\right)^{2}}{L_{1}^{2}} \delta_{1}+\frac{\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]^{2}}{L_{1}^{2} L_{2}^{2}} \delta_{2}\right] \frac{\psi}{H_{1 V}} \tag{A.16}
\end{equation*}
$$

In horizontal direction, $\mathrm{t}=\mathrm{a}$, the half width of the entrance slit, it is also:

$$
\begin{equation*}
\frac{\Delta_{2 h}}{H_{2 h}}=\left[\frac{\left(L_{1}+P\right)}{L_{1}^{2}} \delta_{1}+\frac{\left[L_{1}^{2}-P(L-L 1)\right]^{2}}{L_{1}^{2} L_{2}^{2}\left(L_{1}+P\right)} \delta_{2} \frac{a}{H_{1 h}}\right. \tag{A.17}
\end{equation*}
$$

## A.4. Assumptions

In our system, the parameters have the inequality relationship: L>>L1,L2>>P. All the assumptions we have used above will then be equivalent to:

$$
\begin{align*}
& \delta_{1} \ll L_{1} \\
& \delta_{2} \ll L_{2} \\
& L \delta_{1} \ll L_{1}^{2}-P\left(L-L_{1}-L_{2}\right) \\
& P \delta_{2} \ll L_{1}^{2}-P\left(L-L_{1}-L_{2}\right) \\
& L_{1}^{2} L_{2} \delta_{2} \ll\left[L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)\right]\left[L_{1}^{2}-P\left(L-L_{1}\right)\right] \tag{A.18}
\end{align*}
$$

In Fig. 1, we use a principal line going through the center of F1 to represent the central line of the light bunch and use this line to calculate the spot center deviation D1. This is exactly true for the horizontal case where $t$ is determined by a slit whose center is also the lens center. However, for the vertical case, without any slit, the center line of a point source radiation bunch will be parallel to the optical axis before reaching $\mathrm{F}_{1}$, and that will change $\Delta_{1 \mathrm{v}}$ a little bit by changing $\mathrm{T}=\mathrm{LH}_{1} /\left(\mathrm{L}_{1}+\mathrm{P}\right)$ to $\mathrm{T}=\mathrm{LH}_{1} /\left(\mathrm{L}_{1}+\mathrm{P}\right)-\mathrm{H}_{1}$. Because $\mathrm{L} \gg \mathrm{L}_{1}$, thus $\mathrm{T} \gg \mathrm{H}_{1}$, we can expect that the final change on $\Delta_{1 \mathrm{v}}$ will be very small and all the results above can be used for the vertical image analysis without a large error.

A direct calculation of $\Delta_{1 \mathrm{v}}$ without such approximation leads to a similar result for $\mathrm{P}=0$ case:

$$
\begin{equation*}
\frac{\Delta_{1 V}}{H_{2 V}}=\frac{L-L_{1}}{L_{2}^{2}} \delta_{2}-\frac{1}{L_{1}} \delta_{1} \tag{A.19}
\end{equation*}
$$

## Appendix B

## Connection Between Chromatic Errors and Geometric Errors

## B.1. $\Delta_{2}$ and the depth of field error

It is known that in the vertical direction $\Delta_{2}$ is the dominant term of the image aberration. In the following we will prove that $\Delta_{2}$ is equivalent to the depth of field error of a beam with image length $\Delta_{\mathrm{L}}$.

In Fig. B. $1, \Delta X_{D F}=\psi Z / 2$ is the depth of field error of the source, and $\Delta X_{D F}^{\prime}=\psi^{\prime} Z^{\prime} / 2$ is the depth of field error of the image. For such image system, there are the relations:

$$
\begin{gather*}
Z=Z \beta_{0}^{2} \\
H_{2}=H_{1}\left|\beta_{0}\right| \\
\psi^{\prime}=\frac{t^{\prime}}{X_{20}^{\prime}}=\frac{L_{1}^{2}-P\left(L-L_{1}\right)}{L_{1}\left(L_{1}+P\right)} t / \frac{L_{2}\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)}=\frac{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)}{L_{1} L_{2}\left(L_{1}+P\right)} t  \tag{B.3}\\
=\frac{t}{\left|\beta_{0}\right|\left(L_{1}+P\right)}=\frac{\psi}{\left|\beta_{0}\right|}
\end{gather*}
$$

Figure B. 1 - The image of the depth field error

Where $\beta_{0}, \mathrm{t}, \mathrm{t}$ ' and $\mathrm{X}^{\prime}{ }_{20}$ have the same meanings as in Appendix A. From eqs.(B.1-B.3), it can be found that:

$$
\begin{equation*}
\Delta X^{\prime}{ }_{D F}=\psi^{\prime} Z / 2=\left|\beta_{0}\right| \psi Z / 2=\left|\beta_{0}\right| \Delta X_{D F} \tag{B.4}
\end{equation*}
$$

or:

$$
\begin{equation*}
\frac{\Delta X^{\prime}{ }_{D F}}{H_{2}}=\frac{\Delta X_{D F}}{H_{1}} \tag{B.5}
\end{equation*}
$$

This means: (1) the image will have the same relative field error as the source; (2) When Z ' equals the chromatic aberration longitudinal size $\Delta_{\mathrm{L}}$, the relative field error $\Delta \mathrm{Y}_{\mathrm{DF}} / \mathrm{H}$ should equal the aberration value $\Delta_{2}$ once we put the detector at the center of $\Delta_{\mathrm{L}}$, i.e.:

$$
\frac{\Delta_{2 V}}{H_{2 V}}=\frac{\Delta_{L}}{Z^{\prime}} \frac{\Delta X_{D F}}{H_{1 V}}
$$

B2. $\Delta_{1}$ and the curvature error

Figure B. 2 - The image of the curvature error
$\Delta_{1}$ is the dominant chromatic error in horizontal plane. In the following we will find the connection between $\Delta_{1}$ and beam curvature error.
(i) First, we can see that $\Delta X^{\prime}$ in Fig. B. 2 is compatible to the $\Delta_{1}$ of the chromatic error. As shown in Fig. B.2,

$$
\begin{equation*}
\Delta X^{\prime}=\frac{T+a^{\prime}-H_{S}}{X^{\prime}{ }_{20}+Z} Z \approx \frac{T}{X^{\prime}{ }_{20}} Z \tag{B.6}
\end{equation*}
$$

because $\mathrm{T}=\mathrm{LH}_{\mathrm{Q}} /\left(\mathrm{L}_{1}+\mathrm{P}\right) \gg \mathrm{H}_{\mathrm{S}^{\prime}}$ and $\mathrm{a}^{\prime}$, and $\mathrm{X}^{\prime}{ }_{20} \gg \mathrm{Z}^{\prime}$. Comparing with eq.(A.13), if $\mathrm{Z}^{\prime}$ equals the chromatic shift $\Delta_{\mathrm{L}}\left(\delta_{1}=0, \delta_{2} \neq 0\right), \Delta \mathrm{X}^{\prime}$ will be just the chromatic spot center vertical shift $\Delta_{1}$ :

$$
\begin{equation*}
\Delta_{1}=\frac{\Delta_{1}\left(\delta_{1}=0\right)}{Z^{\prime}} \Delta X^{\prime} \tag{B.7}
\end{equation*}
$$

(ii) The connection between $\Delta X^{\prime}$ and the curvature error $\Delta X_{c}$.

On the left side of Fig. B2, when $\theta$ is small, $\Delta X=Z \theta=R \theta^{2}$, where $R$ is the beam trajectory curvature radius. Meanwhile, $R=\left(\Delta X_{c}+R\right) \cos \theta \approx\left(\Delta X_{c}+R\right)\left(1-\theta^{2} / 2\right) \approx \Delta X_{c}+R-0.5 R \theta^{2}$, Then $\Delta X=2 \Delta X_{c}$. At the same time, there is also the relation:

$$
\begin{equation*}
\Delta X=\frac{\left(H_{Q}+a\right) Z}{L_{1}+P}, \mathrm{H}_{\mathrm{Q}} \text { is the height of } \mathrm{Q} \tag{B.7}
\end{equation*}
$$

With (B.6), (B.7) and $\mathrm{T}=\mathrm{LH}_{\mathrm{Q}} /\left(\mathrm{L}_{1}+\mathrm{P}\right)$, we get:

$$
\frac{\Delta X^{\prime} / H_{2}}{\Delta X / H_{1}} \approx \frac{L Z H_{Q} H_{1}}{X_{20}^{\prime} Z\left(H_{Q}+a\right) H_{2}}=\left|\beta_{0}\right| \frac{H_{Q}}{H_{Q}+a} \frac{L}{X^{\prime}{ }_{20}}=\frac{H_{Q}}{H_{Q}+a} \frac{L L_{1}}{L_{1}^{2}-P\left(L-L_{1}\right)}
$$

or:

$$
\Delta_{1} / H_{2}=\frac{\Delta_{L}\left(\delta_{1}=0\right)}{Z} \frac{H_{Q}}{H_{Q}+a} \frac{2 L L_{1}}{L_{1}^{2}-P\left(L-L_{1}\right)}\left(\Delta X_{C} / H_{1}\right),
$$

or:

$$
\begin{equation*}
\Delta_{1} / H_{2} \approx \frac{\Delta_{L}\left(\delta_{1}=0\right)}{Z} \frac{L L_{1}}{L_{1}^{2}-P\left(L-L_{1}\right)}\left(\Delta X_{C} / H_{1}\right) \quad \text { when } \mathrm{a} \approx \mathrm{H}_{\mathrm{Q}} \tag{B.8}
\end{equation*}
$$

In our system, when $\mathrm{P}=0$, equation (B.8) means:

$$
\begin{equation*}
\Delta_{1} / H_{2} \approx 2.36\left(\Delta X_{C} / H_{1}\right) \tag{B.9}
\end{equation*}
$$

This is the relationship between $\Delta_{1}$ and the relative curvature error.

Because the curvature error is very small, only $\sim 0.024$ times the total measurement error [1], we can expect that $\Delta_{1}$ aberration error will be $\sim 5$ per cent of the total measurement error.
(iii) Although from (B.8) there will be $\left(\Delta \mathrm{X}^{\prime} / \mathrm{H}_{2}\right) /\left(\Delta \mathrm{X} / \mathrm{H}_{1}\right) \approx 10$ for $\mathrm{P}=0$, the image relative curvature error is the same as the source one. This can be explained as follows: the optical rays of SA, AT' are from point $S$; they should go to $S^{\prime}$. Meanwhile SA, AT' can be treated as coming from Q and they should reach $\mathrm{Q}^{\prime}$ too. So, $\mathrm{T}^{\prime}, \mathrm{Q}^{\prime}$ and $\mathrm{S}^{\prime}$ are located at one line; $\Delta \mathrm{X}^{\prime} \mathrm{C}$ should be the curvature error caused by the ray to $\mathrm{S}^{\prime}$. Because $\mathrm{S}^{\prime}$ and $\mathrm{Q}^{\prime}$ are also the images of S and Q , $\Delta \mathrm{X}^{\prime}{ }_{\mathrm{C}}=\left|\beta_{0}\right| \Delta \mathrm{X}_{\mathrm{C}}$.

What is the reason for $\left(\Delta \mathrm{X}^{\prime} / \mathrm{H}_{2}\right) /\left(\Delta \mathrm{X} / \mathrm{H}_{1}\right) \approx 10$ but $\left(\Delta \mathrm{X}_{\mathrm{c}}^{\prime} / \mathrm{H}_{2}\right) /\left(\Delta \mathrm{X}_{\mathrm{c}} / \mathrm{H}_{1}\right)=1$ ? This is because there are different magnifications at point Q and S and the image of the beam trajectory is no longer a circle at all.

Actually, with optical formulas we can prove that the image points $S^{\prime}, Q^{\prime}$ are located at the same line coming from $T^{\prime}$ although there is a big difference between $\Delta X$ and $\Delta X^{\prime}$. (Any one interested may read the verification).

On one hand,

$$
\frac{T-H_{Q^{\prime}}}{X_{20}^{\prime}}=\frac{T+a^{\prime}-\left|\beta_{0}\right| H_{Q}}{X_{20}^{\prime}}
$$

Substitute a instead of a' with eq.(A.14),

$$
\begin{equation*}
\frac{T^{\prime}-H_{Q^{\prime}}}{X_{20}^{\prime}}=\frac{T+\frac{L_{1}^{2}-P\left(L-L_{1}\right)}{L_{1}\left(L_{1}+P\right)} a-\left|\beta_{0}\right| \frac{T\left(L_{1}+P\right)}{L}}{\frac{L_{2}\left[L_{1}^{2}-P\left(L-L_{1}\right)\right]}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)}}=T\left[\frac{1}{L_{2}}-\frac{1}{L}\right]+\frac{1}{\left|\beta_{0}\right|\left(L_{1}+P\right)} a \tag{B.10}
\end{equation*}
$$

On the other hand, the vertical magnification at point $\mathrm{S}^{\prime}$ will be:

$$
\beta_{Z}=-\frac{L_{1} L_{2}}{L_{1}^{2}-(P-Z)\left(L-L_{1}-L_{2}\right)} \approx-\frac{L_{1} L_{2}}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)}+\frac{Z L_{1} L_{2}\left(L-L_{1}-L_{2}\right)}{\left[L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)\right]^{2}}
$$

or:

$$
\begin{equation*}
\Delta \beta=\beta_{Z}-\beta_{0}=\frac{Z L_{1} L_{2}\left(L-L_{1}-L_{2}\right)}{\left[L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)\right]^{2}}=\left|\beta_{0}\right| \frac{Z\left(L-L_{1}-L_{2}\right)}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)} \tag{B.11}
\end{equation*}
$$

Then,

$$
\begin{gathered}
\frac{H_{Q^{\prime}}-H_{S^{\prime}}}{Z}=\frac{\left|\beta_{0}\right| H_{Q}-\left|\beta_{Z}\right|\left(H_{Q}-\Delta X\right)}{Z}=\frac{\Delta X\left|\beta_{0}\right|+H_{Q} \Delta \beta}{Z} \\
\approx \frac{\left|\beta_{0}\right| Z \frac{\left(H_{Q}+a\right)}{L_{1}+P}+\left|\beta_{0}\right| Z \frac{L-L_{1}-L_{2}}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)} H_{Q}}{Z} \\
=\frac{H_{Q}}{\left|\beta_{0}\right|}\left(\frac{1}{L_{1}+P}+\frac{L-L_{1}-L_{2}}{L_{1}^{2}-P\left(L-L_{1}-L_{2}\right)}\right)+\frac{a}{\left(L_{1}+P\right)\left|\beta_{0}\right|} \\
=\frac{H_{Q}\left(L-L_{2}\right)}{L_{2}\left(L_{1}+P\right)}+\frac{a}{\left(L_{1}+P\right)\left|\beta_{0}\right|} \\
=T\left(\frac{1}{L_{2}}-\frac{1}{L}\right)+\frac{a}{\left(L_{1}+P\right)\left|\beta_{0}\right|}
\end{gathered}
$$

then:

$$
\begin{equation*}
\frac{H_{Q^{\prime}}-H_{S^{\prime}}}{Z^{\prime}}=\frac{T-H_{Q^{\prime}}}{X_{20}^{\prime}} \tag{B.12}
\end{equation*}
$$

This means $\mathrm{T}^{\prime}, \mathrm{Q}^{\prime}$ and $\mathrm{S}^{\prime}$ are on the same line.

## Appendix C

## Flatness of the Mirror Between the Lenses.

The schematic drawing of the mirror distortion between the two lenses is shown in Fig. C.1. Because of the distortion by the mirror, the down-stream optical equipment feels the rays coming from point source Q as if coming from Q '.

First, let us look at the longitudinal image shift by the spherical curved mirror. From Appendix A , we know that the distance from the image of Q to the mirror will be:

Figure C. 1 - Distortion of the $\mathrm{F}_{1}$ image

$$
\begin{equation*}
x=X_{1}^{\prime}-S=\frac{f_{1} X_{1}}{f_{1}+X_{1}}-S \tag{C.1}
\end{equation*}
$$

where $\mathrm{X}_{1}=-\left(\mathrm{P}+\mathrm{L}_{1}\right)$. Because of the mirror distortion, the error on x will be (see eq.(3.6))

$$
\begin{equation*}
\Delta x=16\left(\frac{x}{d}\right)^{2} h \sin ^{-1} \alpha \tag{C.2}
\end{equation*}
$$

When this error equals the source longitudinal shift $\Delta \mathrm{P}$,

$$
\begin{equation*}
\Delta x=\left[\frac{f_{1}\left(X_{1}+\Delta P\right)}{f_{1}+X_{1}+\Delta P}-S\right]-\left[\frac{f_{1} X_{1}}{f_{1}+X_{1}}-S\right]=\left(\frac{f_{1}}{f_{1}+X_{1}}\right)^{2} \Delta P \tag{C.3}
\end{equation*}
$$

we can get,

$$
\begin{equation*}
h=\frac{\sin \alpha}{16}\left(\frac{d}{x}\right)^{2}\left(\frac{f_{1}}{f_{1}+X_{1}}\right)^{2} \Delta P \approx \frac{\sin \alpha}{16}\left(\frac{d}{L_{1}}\right)^{2} \Delta P, \text { when } \mathrm{x} \gg \mathrm{~S} \tag{C.4}
\end{equation*}
$$

Secondly, for the vertical case, from Fig. C.1, there are the relations,

$$
\begin{gathered}
\theta=\frac{d}{S} \\
\theta+\Delta \theta=\frac{d}{S-\Delta S} \approx \frac{d}{S}+\frac{d}{S^{2}} \Delta S \Rightarrow \Delta \theta=\frac{d}{S^{2}} \Delta S \\
H=\left(L_{1}+P\right) \theta \\
\Delta H=\left(L_{1}+P\right) \Delta \theta \\
\Rightarrow \frac{\Delta H}{H}=\frac{\Delta \theta}{\theta}=\frac{\Delta S}{S}
\end{gathered}
$$

From eq.(3.6), we know that,

$$
\begin{align*}
& h=\frac{\sin \alpha}{16}\left(\frac{d}{S}\right)^{2} \Delta S  \tag{C.5}\\
& \Rightarrow h=\frac{\sin \alpha 1}{16} \frac{d^{2}}{S} \frac{\Delta H}{H}
\end{align*}
$$

For instance, for M3 mirror, if the size is $200 * 400 \mathrm{~mm}, \mathrm{~S}=8127 \mathrm{~mm}, \alpha=8.715^{\circ}$, $\Delta \mathrm{H} / \mathrm{H}=0.026$, the half vertical chromatic aberration, $\Delta \mathrm{P}=3 \mathrm{~mm}$, one third of the beam length (remember the beam chromatic spot length is one third of the beam image length). Along the vertical direction: $\mathrm{d}=400 \mathrm{~mm}, \alpha=8.715^{\circ}$, we get $\mathrm{h}=0.0048 \mathrm{~mm} \approx 8 \lambda$ with (C.5) and $\mathrm{h}=0.0009 \mathrm{~mm}=1.5 \lambda$ with (C.4); along the horizontal direction, $\mathrm{d}=200 \mathrm{~mm}, \alpha=90^{\circ}, \Delta \mathrm{H} / \mathrm{H}=$ 0.005 , the half horizontal chromatic aberration, we get $\mathrm{h}=0.0015 \mathrm{~mm} \approx 2.5 \lambda$ with both (C.5) and (C.6). Here $\lambda=6000 \AA$.

For M5, we suppose the size will be $150 * 150 \mathrm{~mm}, \mathrm{~S}=25000 \mathrm{~mm}, \Delta \mathrm{P}=3 \mathrm{~mm}, \alpha=45^{\circ}$ and $\Delta \mathrm{H} / \mathrm{H}=0.026$ in the vertical direction while $\alpha=90^{\circ}$ and $\Delta \mathrm{H} / \mathrm{H}=0.005$ in the horizontal direction. We can get $\mathrm{h} \approx 1.5 \lambda$ with (C.5) and $\mathrm{h} \approx \lambda$ with (C.4) in vertical direction and $\mathrm{h} \approx 0.5 \lambda$ by (C.5) in the horizontal direction.

This suggests the "spherical" flatness of such mirrors should be better than $\lambda$.
