ALIGNMENT OPERATIONS FOR THE DAΦNE UPGRADE

M. Esposito, C. Milardi, M. Paris, F. Sgamma, S. Tomassini, M. Troiani

Introduction

In 2007 the DAΦNE team has realized an upgrade of the collider based on the novel crabbed waist collision scheme [1]. The upgrade is aimed at pushing the luminosity towards $10^{33} \text{ cm}^{-2} \text{ s}^{-1}$. This has required a substantial aligning work in order to realize the new magnetic layout (Figure 1) of the machine.

First of all a complete redefinition of the network of reference nodes has been accomplished. Secondly the alignment of the accelerator components has been either done anew or simply checked and readjusted when necessary.

In this paper the procedure and the instruments used for the measurement and redefinition of the reference network are described. Results are shown and a comparison between new and old positions of the network nodes is discussed. At last the fiducialisation data necessary for the alignment of the magnetic components is listed.

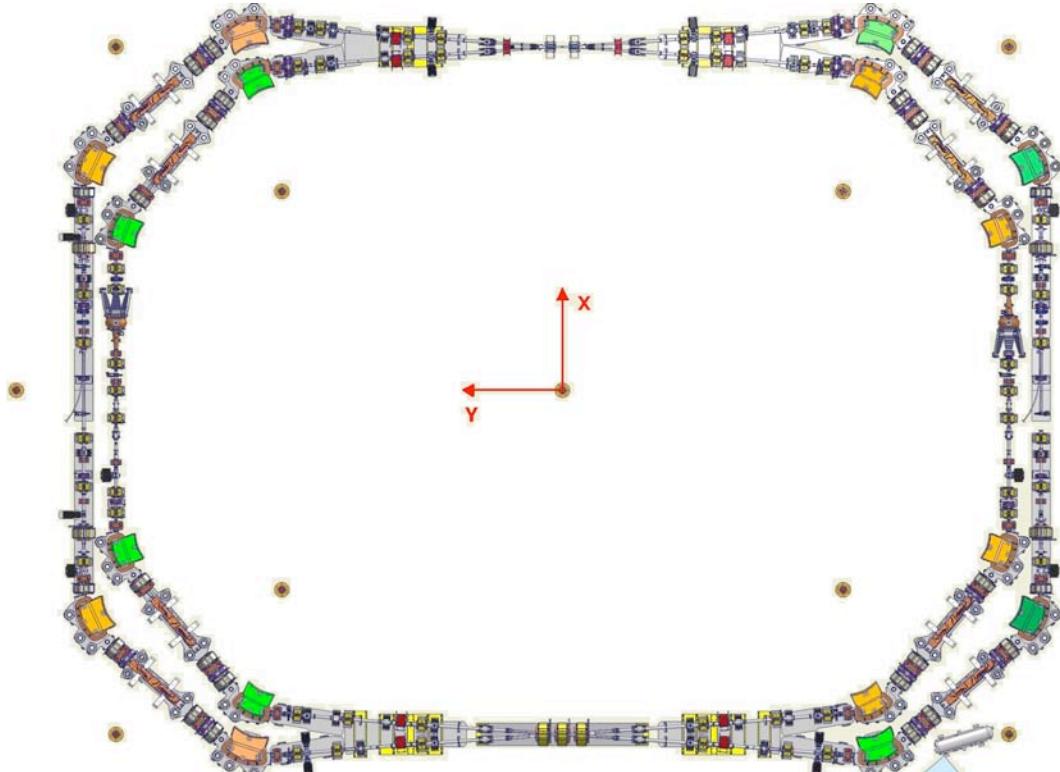

Figure 1: DAΦNE Accelerator.

1. Requalification of the Reference Network

A network of reference nodes had been realized in the DAΦNE Hall back in 1997. This Network [2] is composed of 15 principal nodes (Figure 2), each one consists of a permanent pillar equipped with a survey reference socket (Figure 3), and of 64 additional nodes (4 reference sockets fixed on top of each one of the 16 total dipoles).

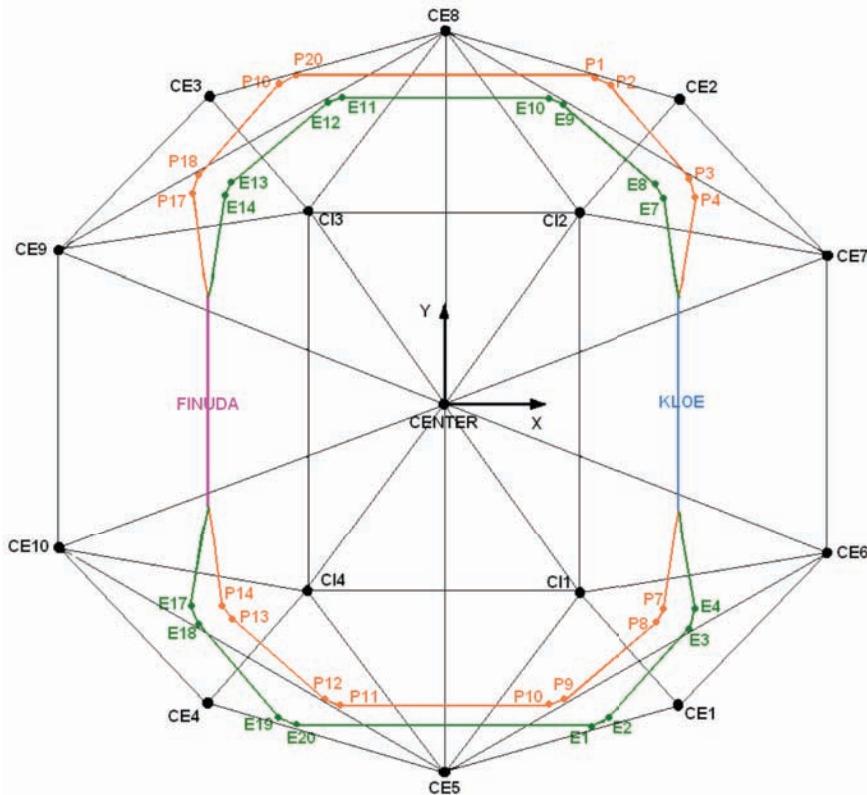

Figure 2: DAΦNE Reference Network and DAΦNE Coordinate System (DCS).

The availability of more advanced measuring instruments, along with the necessity of checking the building stability and precisely determining the position of some dipoles that have been moved, suggested the importance of a complete campaign of measurements aimed at verifying and, if necessary, updating the 3D coordinates of the reference nodes.

The measurements have been realized using a Leica Laser Tracker LTD 840 [3], the data collected have then been analysed and treated by means of Leica Axyz software. The entire campaign required 10 measuring stations strategically positioned inside the DAΦNE Hall. The choice of the optimal position for each station has been made with the purpose of maximizing the number of visible nodes within an acceptable measuring distance and assuring sufficient node measurement redundancy among the different stations. The latter is essential to orient the network, i.e. to link the stations together and visualize all the points in a unique base coordinate system. The environmental conditions (noise generated by cooling devices and by human activity, temperature instability, air conditioning) suggested to set a value of approximately 15m for the maximum acceptable measuring distance. The data value for each point comes from an average of 200 measurements every 0.02s. All the measurements with an RMS value of the residuals greater than 0.03 mm have been rejected. The elaboration of the collected data consists in the orientation of the network and the definition of the DAΦNE Coordinate System (DCS). It takes all the existing measurements, or a sub-set edited by the user, and builds, mathematically, a measurement

network. This operation is performed in two steps: an initial and approximate estimation of station parameters and a final and optimized estimation, known as bundle adjustment. The initial estimation of values makes use of a mathematical 3D transformation that takes into account only the bare minimum data required. The bundle adjustment is a least squares optimization. It takes the “bundles” of instrument pointings and makes successive adjustments to the network parameters until there is a best fit between the mathematical model of the network and the actual measurements. The output is then displayed along with some details such as the number of iterations, the pointing error for each point and the RMS value of the perpendicular and spatial offsets of the calculated point locations from the measured pointings. In our case the orientation of the network has been solved in 3 iterations with a maximum pointing error of 0.124 mm and an RMS value of 0.033 mm.

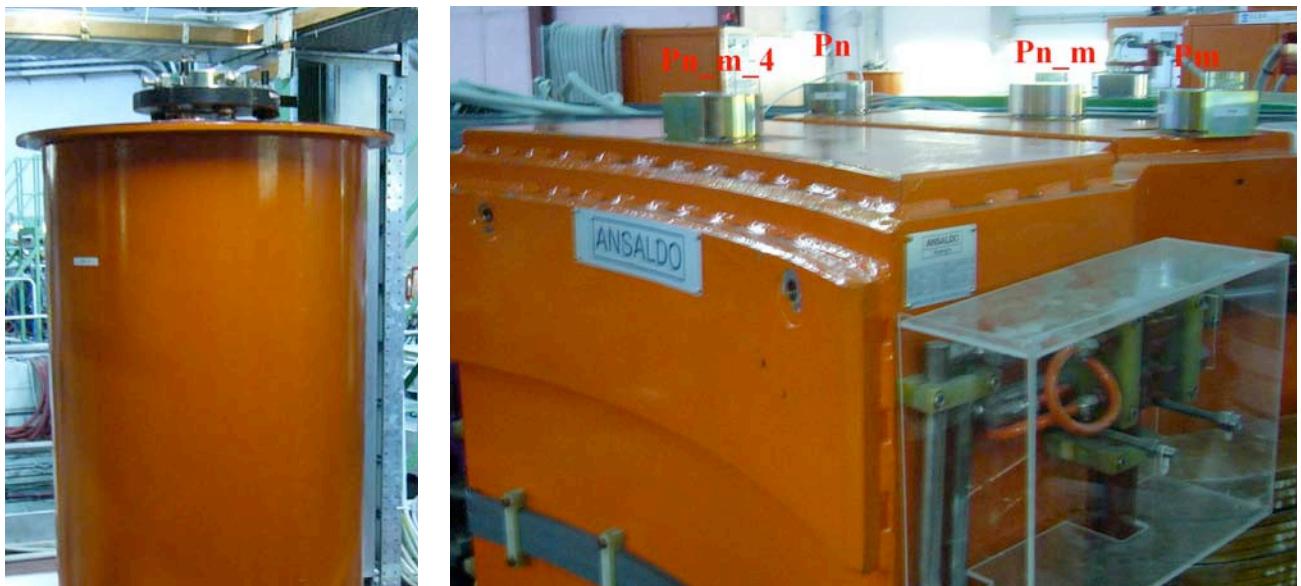

Figure 3: Pillar and Dipole Equipped with Reference Sockets.

The coordinates of the network nodes are shown in Table 1, Table 2 and Table 3. They are referred to the DAΦNE Coordinate System (DCS) that is the right handed Cartesian coordinate system shown in Figure 2.

The six parameters necessary to define the DCS in the Axyz program are the following coordinates:

	X	Y	Z
Center	0	0	717.47
CI2	6750.00	-	715.67
CI3	-	-	716.14

The height of the center pillar over the beam plane and the Δx of node CI2 have been taken from the 1997 DAΦNE Coordinate System. The vertical offsets of CI2 and CI3 with respect to the center node have been measured during this alignment campaign (leica level).

Table 3: Coordinates of the DAΦNE Reference Network Nodes (Positron Dipole Sockets)

The four dipoles on the external ring, adjacent to the interaction regions, are marked in grey because they have been modified and moved [4] after the requalification of the network. Therefore the coordinates of those nodes do not correspond to their current positions (June 2008).

A comparison between the 2007 network requalification and the first measurements performed in 1997 by means of invar wires and optical levels shows that a not negligible variation of the network occurred across these years. In Diagram 1 we can see the horizontal components of the pillar node shifts from their original positions. We can notice peak values of up to 2 mm with a mean value of approximately 0.5 mm.

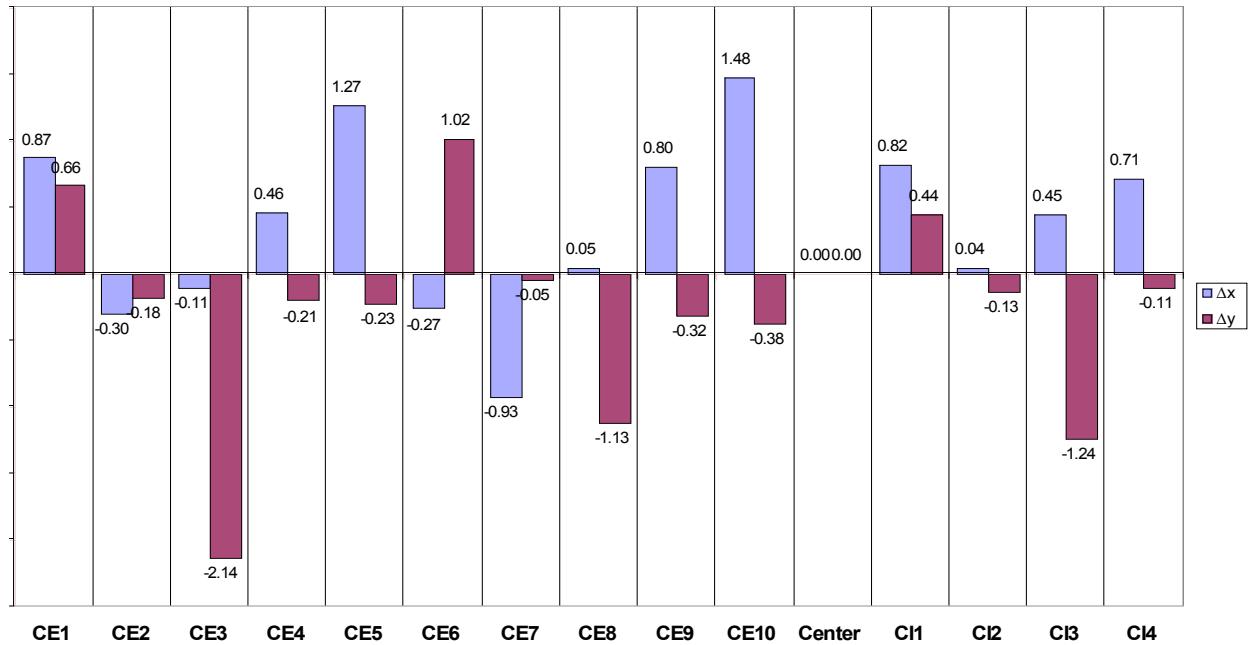

Diagram 1: Pillar Horizontal Movements (1997→2007).

Diagram 2 shows the height variation of the main pillar nodes in the last ten years. The fluctuations are of the same order of magnitude as for horizontal shifts. No general tendency is observable.

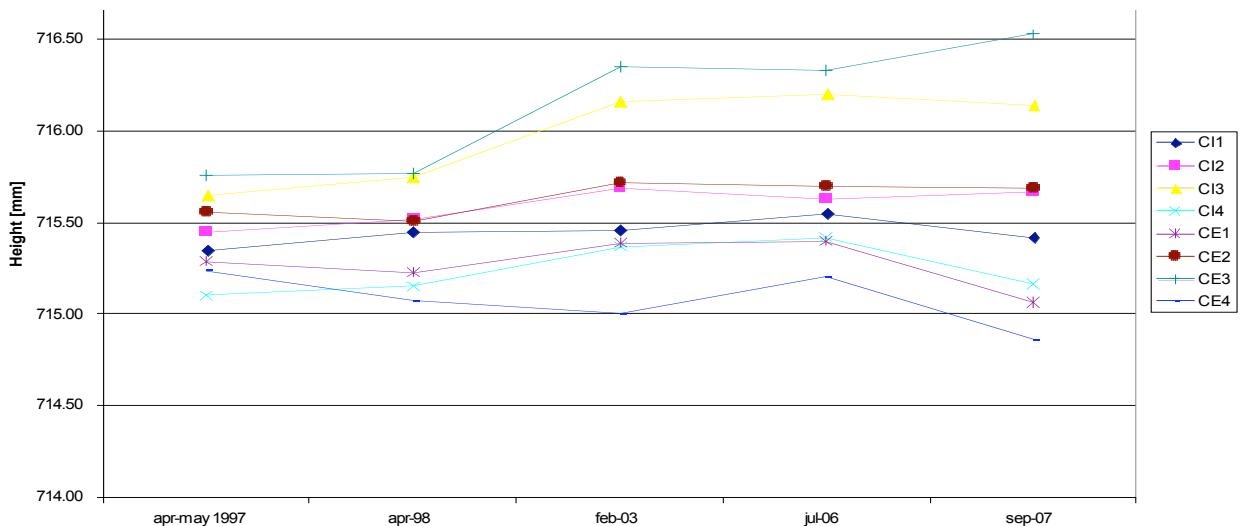

Diagram 2: Height Variations of Pillar Nodes.

2. Alignment of the Accelerator Components

The upgrade of DAΦNE required a realignment of most of the accelerator components. The alignment procedure required the use of a laser tracker, in some cases 2 laser trackers simultaneously, to make the process easier and quicker. Various other tools such as a level, to control the tilt angle, and aligning plates (Figure 4) have been used. The latter are metallic plates with two sockets (fiducial markers A and B as shown in Figure 5) mounted on translation tables moved by means of micrometric graduated screws. Each type of magnet (Small Quadrupoles, Large Quadrupoles, Large Aperture Quadrupoles, Small Sextupoles and Large Sextupoles) requires its own aligning plate, except for the Dipoles, Corrector Magnets and the Permanent Magnet Quadrupoles which have fiducial markers fixed to their external structure. These components do not need any fiducialisation. The position of the markers with respect to their axis can be taken from the mechanical design.

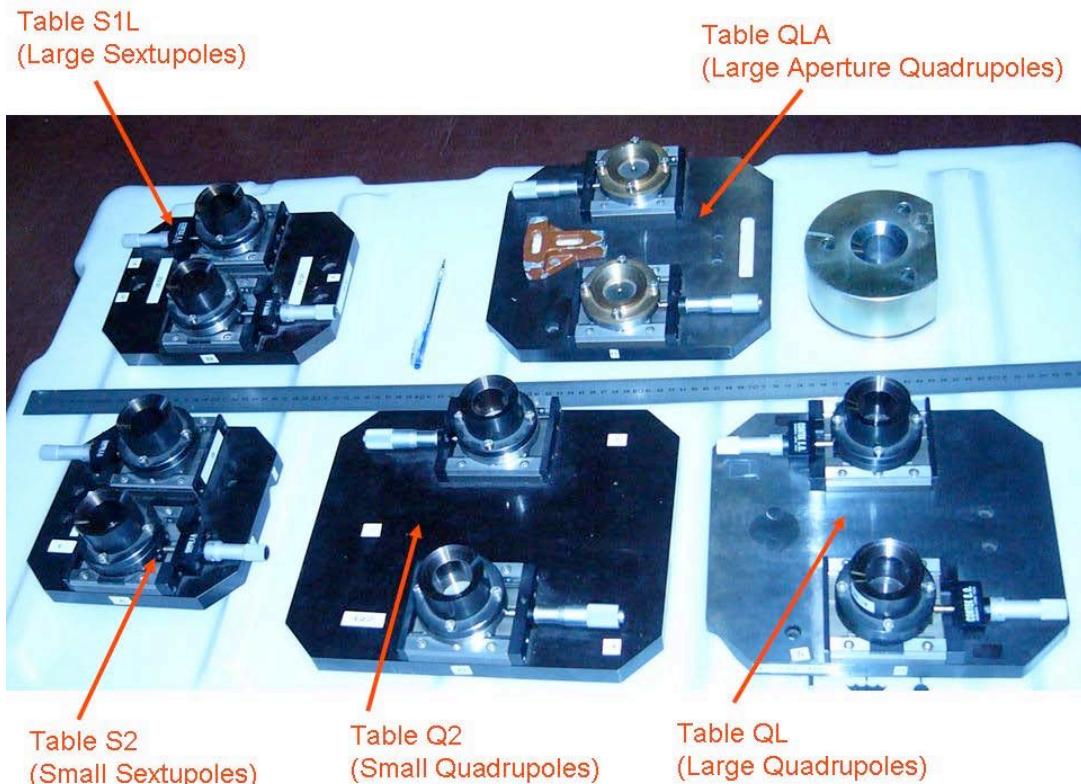

Figure 4: Aligning Plates.

The data for the alignment of the magnets using aligning plates has been retrieved from the fiducialisation work carried out in 1997 [5]. It contains the values of the screw positions necessary to place markers A and B in the vertical plane containing the magnetic axis, the height of these two fiducials above the axis and also the tilt angle to fix completely all degrees of freedom. The values taken from references [5] and [6] have been corrected by taking into account the use of different targets (a 1.5 inch corner cube reflector CCR necessary for laser tracker measurements, instead of a 3.5 inch Taylor Hobson sphere used previously with optical instruments) and are displayed as coordinates of a local right-handed Cartesian coordinate system (LCS) fixed to the magnet having:

- origin in the center of the magnet
- magnetic axis of the magnet as x axis (with positive direction pointing from A to B)
- vertical axis as z axis (with positive direction pointing upwards).

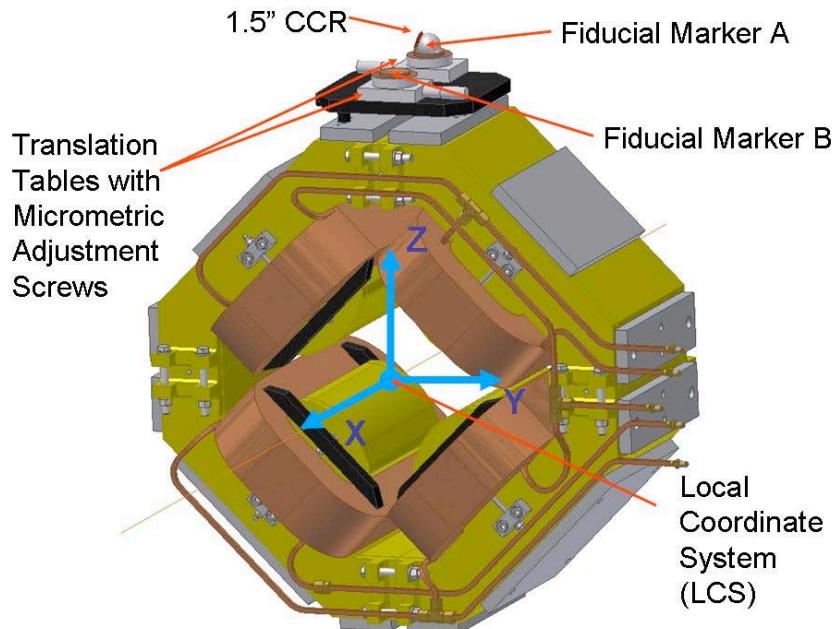

Figure 5: Magnet Local Coordinate System (LCS) and Alignment Tools.

During the DAΦNE upgrade alignment operations we have started to fiducialise three additional fiducial markers for each quadrupole and sextupole magnet. These new fiducials (M1, M2 and M3 in Figure 6) are embedded in the external structure of the magnets.

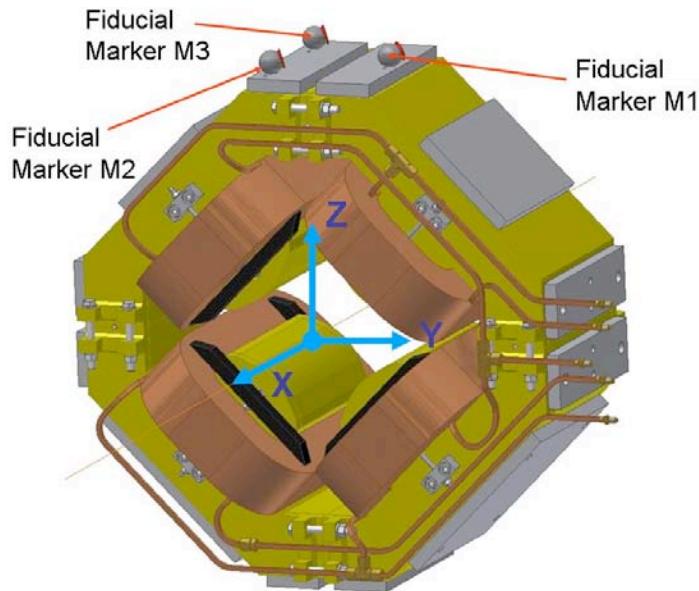

Figure 6: Fiducials M1, M2 and M3.

Knowing the position of these fiducials with respect to the magnetic axis, we will be able to perform the alignment without the use of aligning plates and levels. Nevertheless this work is still in progress, therefore the fiducialisation data for markers M1, M2 and M3 is available only for few magnets.

All the fiducialisation data for each magnet (LCS coordinates of the Fiducials, screw positions and tilt angle around the magnetic axis) are listed in the tables below. A zero value of the tilt angle means that the aligning plate must be in horizontal position; a positive value means that it must be rotated in counter-clockwise direction, observing it from the side of the cooling water connections.
