Why X-ray polycapillary optics could be useful in magnetic fusion plasmas ?

Preliminary results for using polycapillaries as imaging optics for extended sources (plasmas)

Possible schemes to be used in soft X-ray diagnostics for magnetic fusion plasmas

# What is a magnetic fusion plasma?

Central temperature  $\sim 1 \div 20 \text{ KeV}$ Edge temperature  $\sim 10 \div 50 \text{ eV}$ 

#### Low density

central density ~  $10^{20}$  particles/m<sup>3</sup> edge density ~  $10^{18}$  particles/m<sup>3</sup>

High power density (~ MW/m<sup>3</sup>)

# **Experiments (Tokamak)**

#### "world" tokamak (ITER)

#### "Domestic" experiment (FTU)

1.65 m<sup>3</sup> a= 0.3 m R=0.93 m

"Continental" (european) tokamak (JET)

> 50 m<sup>3</sup> a=0.96 m R=2.89 m

490 m<sup>3</sup> a=2 m R=6.2 m P fus = 500 MW

#### Surfaces of SXR isoemissivity Poloidal cross section

# **Relevancy of soft X-ray emissions**

$$B_{i} = \iint_{l_{i}E} \sum_{z} \left[ W_{ff}^{z} + W_{fb}^{z} + W_{bb}^{z} \right] \Omega_{D} \varepsilon_{D}(E) dE dI$$

#### SXR emissivity W ~ $10^{16} \div 10^{18}$ ph/(s m<sup>3</sup> sr) [1-20 keV]

- Plasma emits broadband: microwaves, IR, visible, VUV, SXR, Hard-X, gamma, neutrons. Particles
- SXR emissions carry a lot of information over the entire plasma, allowing fast (ms to microsecond) monitoring in 3D of fluid and kinetics processes, and impurity content as well.
- SXR diagnostics in MCF does not require high spatial resolution

# Polycapillary optics for magnetic fusion plasmas

# Preliminary tests with polycapillaries (September 2010) (Laboratory LNF-INFN)

Setup for radiography of the mask (sample)

Medipix 256 X 256 pixels Pixels 55 μm X 55 μm area 1.5 cm X 1.5 cm Silicon semiconductor Medipix2 developed by the Medipix2 collaboration at CERN [] X. Llopart et al., /IEEE Trans. //Nucl. Sci./, Vol. 49 (5) (2002) 2279]

# Setup for imaging of a mask

## Divergence full-lens and half-lens

Len	Length	Sect <sub>input</sub>	Sect output	F <sub>input</sub>	Foutput
Full-lens	11.3 cm	4 mm	4 mm	5.65 cm	4.4 cm
Semi-lens	5.8 cm	4 mm	6 mm	9.16 cm	

#### Transmission (full lens)

T=Io / Ii ~ 6 %

# Imaging of a pin (500 μm) X-ray tube (Mo anode) at 25 kV

## Imaging of a Needle

#### Image (magnified) with full lens

#### Mesh with holes 400 $\mu m$

#### **Magnification 6 X**

#### Rectangular grid with wires 100 $\mu$ m pitch 1.3 mm

#### Images of the mesh with holes, at different magnifications

#### Imaging with a detector (GEM) of large area at large distance

Images with Gem Pixels Detector with a linear array of 128 pixels 500 um X 500 um Images are obtained with a scan in direction perpendicular to the array

![](_page_17_Picture_2.jpeg)

# "Cromatic aberrations"

![](_page_17_Figure_4.jpeg)

#### Relative Transmission (r2/r0) vs Energy

![](_page_17_Figure_6.jpeg)

# Imaging with half-lens

![](_page_18_Figure_1.jpeg)

![](_page_19_Figure_0.jpeg)

Half-lens is an excellent light collector, very low divergence (quasi parallel beam).Perfect to move the detector far away.Pillar (cilindric lens, dia 4-5 mm) is highly directive.Fibers (straight policapillaries , dia 1 mm) can be bent

![](_page_20_Figure_1.jpeg)

# CONCLUSIONS

Optical properties (focus, transmission, optical and chromatic aberrations, divergence) for half lens and full lens have been measured, in the SXR range 5-25 keV

Imaging properties have been demonstrated for full-lens, with a resolving power of about 100, for distances much larger than the focal distance

Polycapillary optics could be very useful for SXR diagnostics (imaging and tomography) for Magnetic Fusion Plasmas.

After these preliminary studies, experiments should be done in a tokamak
