

Machine Requirements for a Neutrino Factory

Patrick Huber

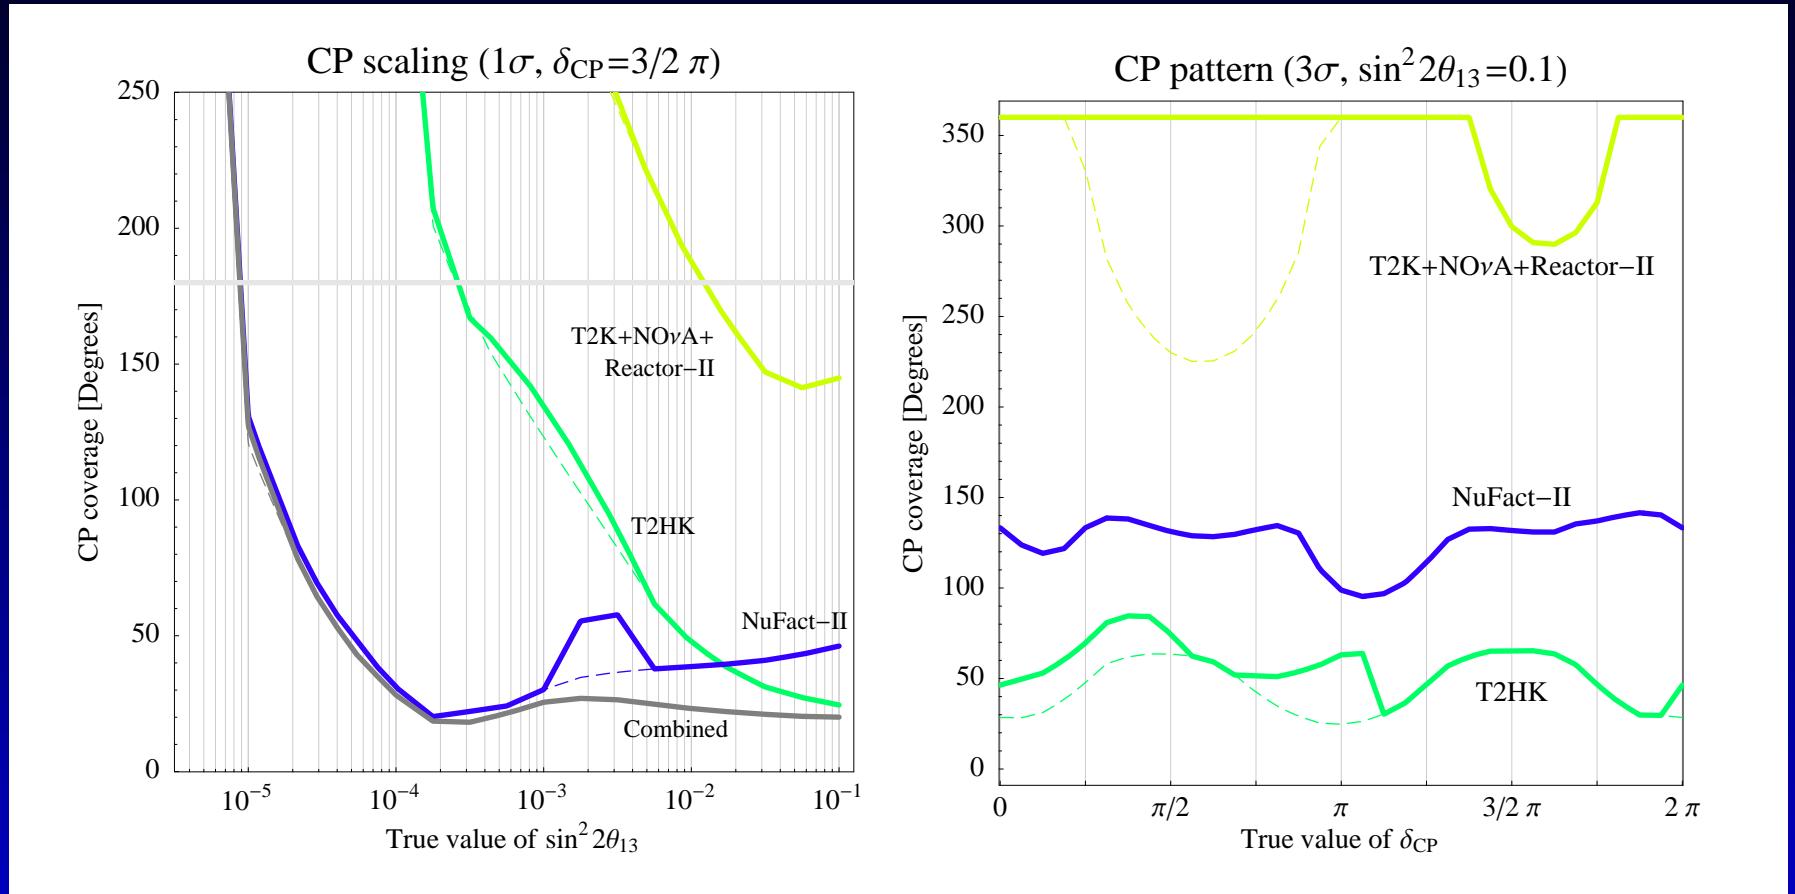

University of Wisconsin

7th International Workshop on Neutrino Factories and Superbeams

Laboratori Nazionali di Frascati

Frascati, Italy

Sensitivity

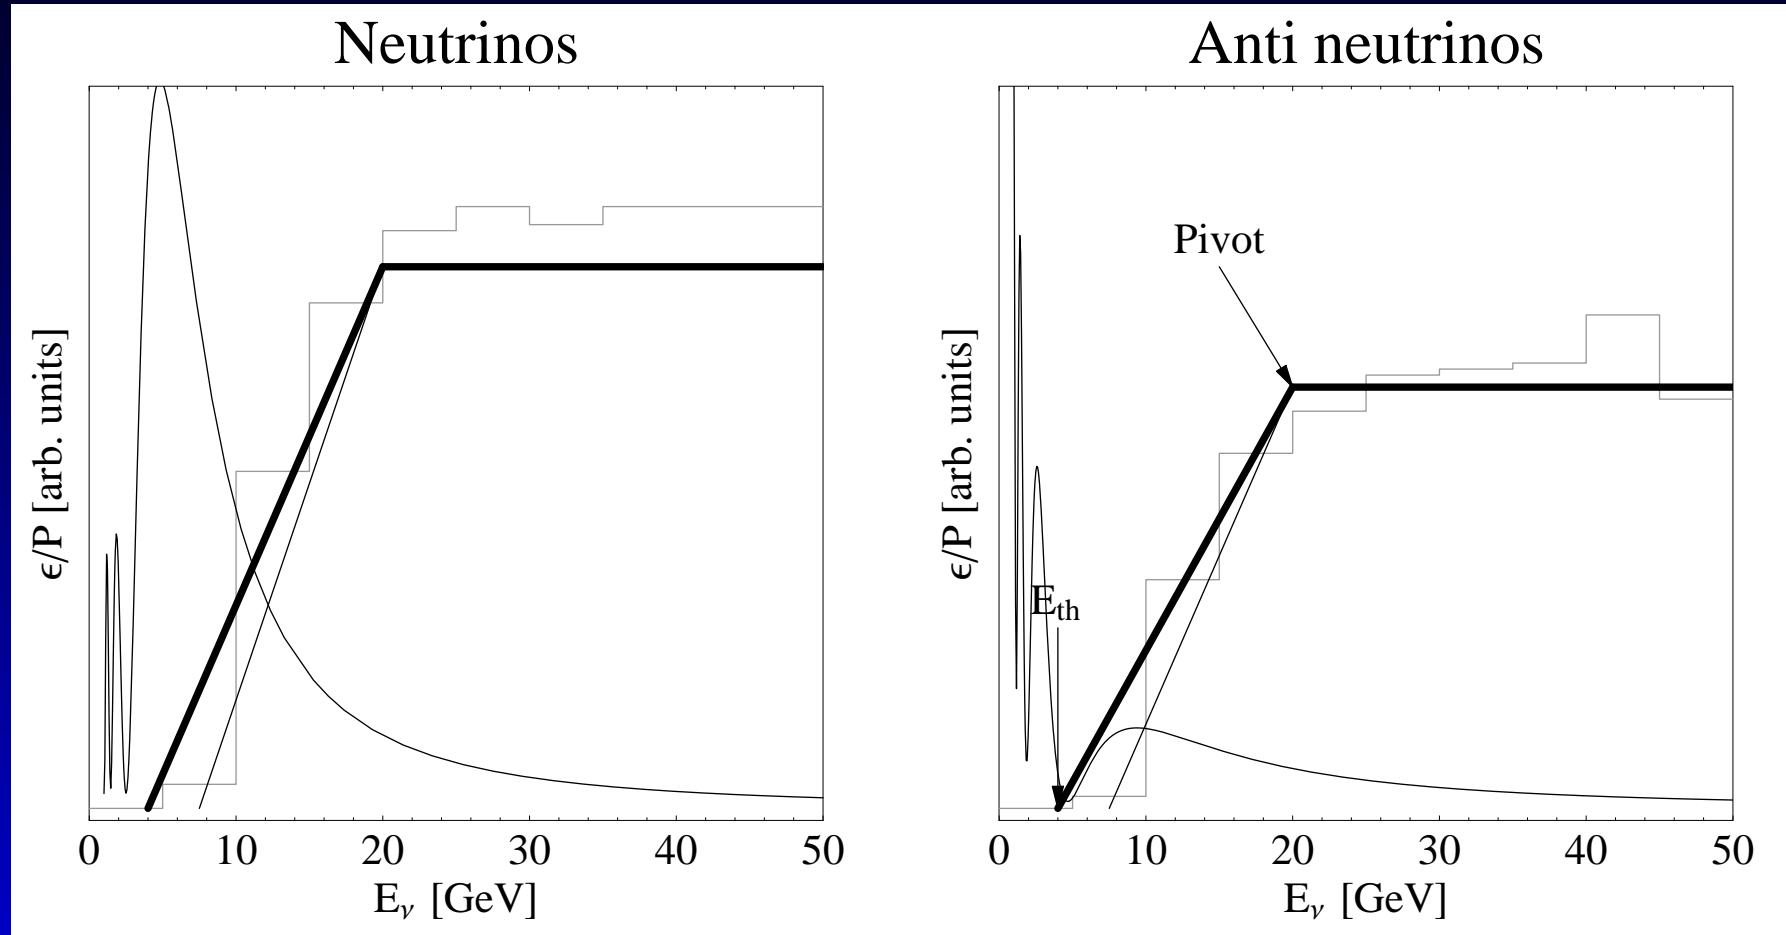

from Huber *et al.*, 2005.

large θ_{13} performance dominated by matter density –
ask geo-physicists!

Canonical numbers

- $E_\mu = 50 \text{ GeV}$
- 10^{21} useful decays/a,
- 4 y ν and $\bar{\nu}$ running each
- 50 kt detector
- Energy given by detector threshold
- Factor 2 in luminosity probably okay

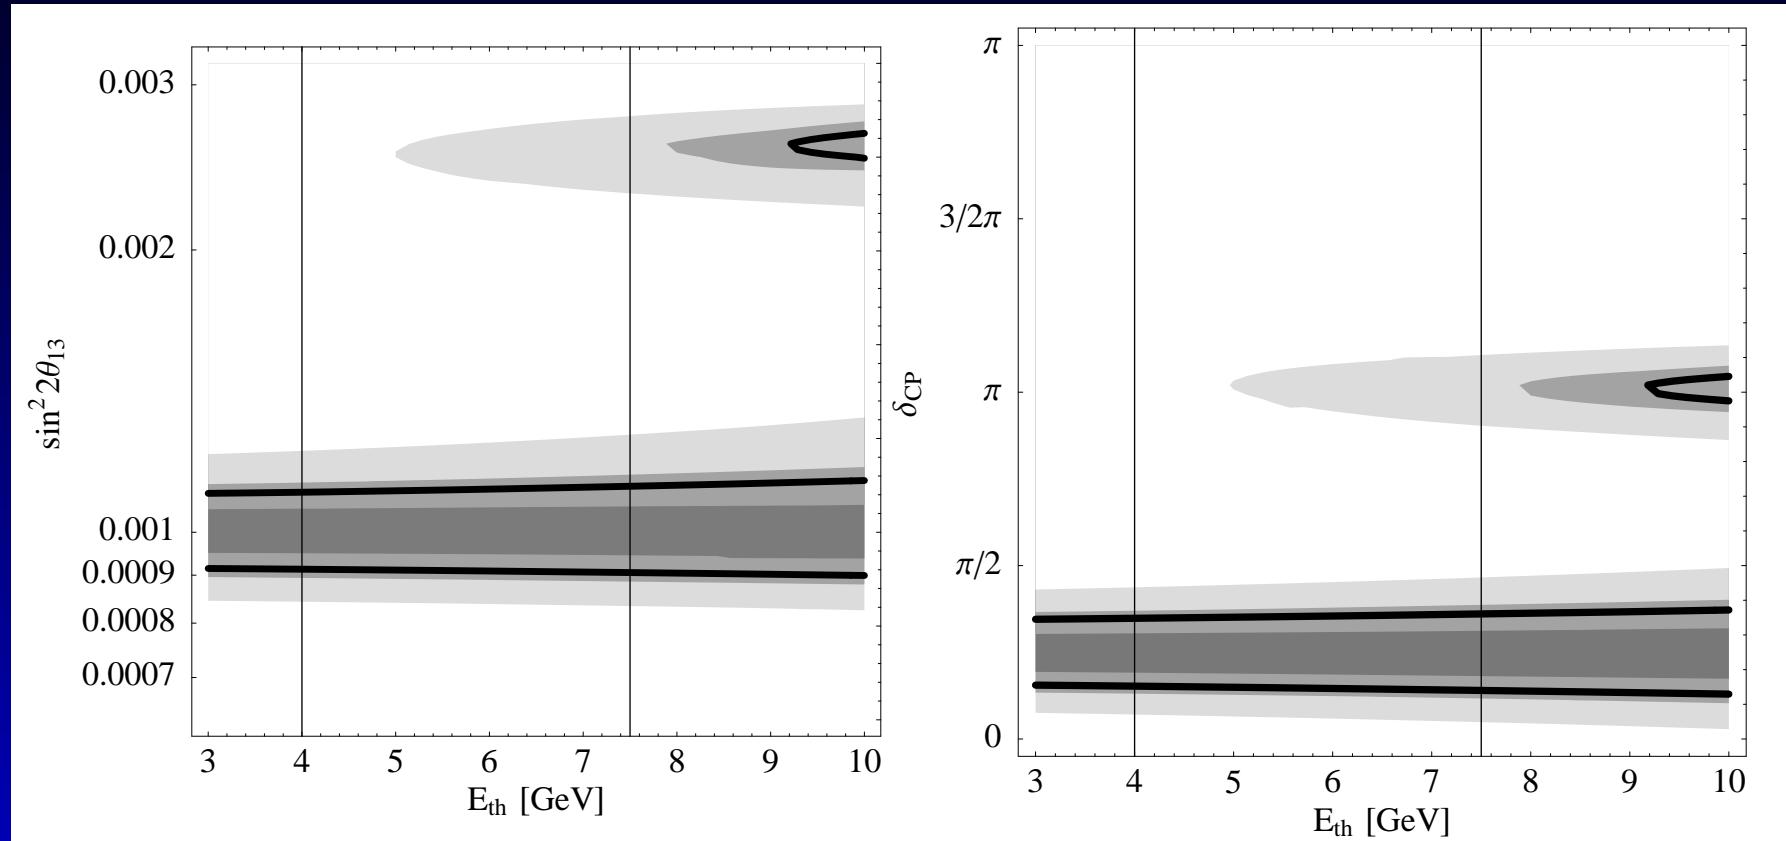

Threshold - I

grey curves taken from Cervera *et al.*, 2000.

thick black line corresponds to Huber *et al.*, 2002.

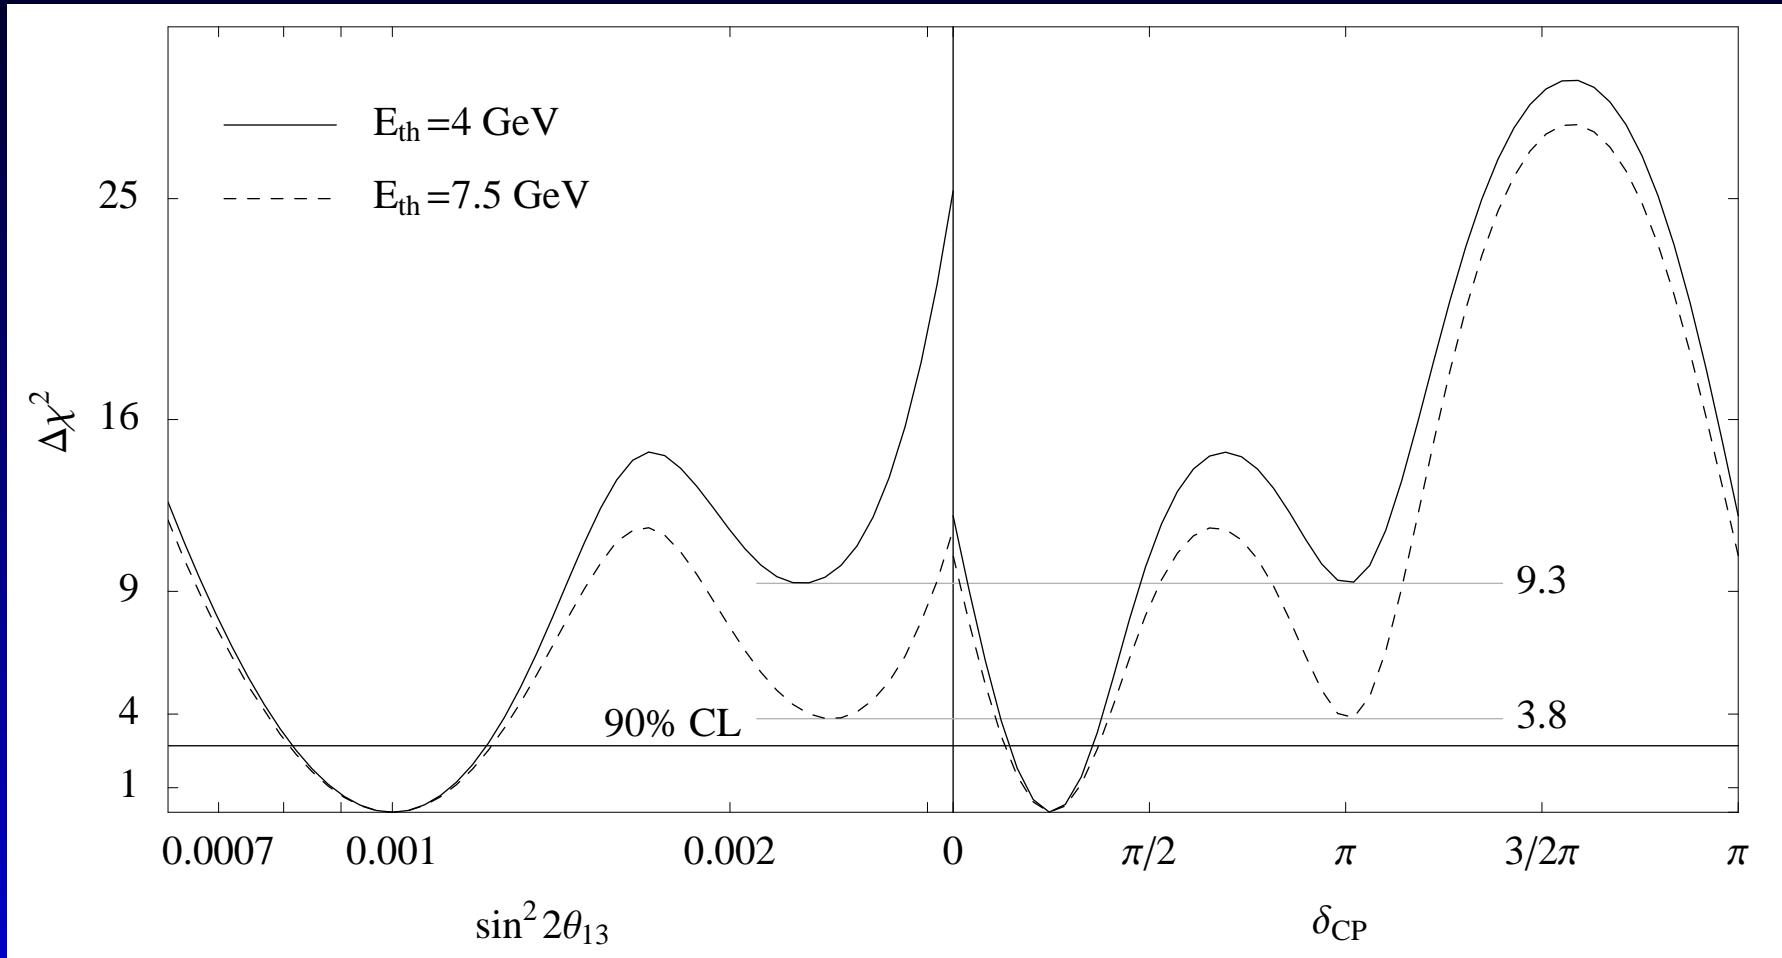

Threshold - II

from Huber *et al.*, 2002.

Impact of intrinsic degeneracy strongly depends on the threshold

Threshold – III

from Huber *et al.*, 2002.

Even small improvements help a lot!

Conclusion

Reducing the neutrino energy
requires re-considering the detector –

threshold and energy resolution

otherwise we need

$E_\mu = 50 \text{ GeV}$ and 10^{21} useful decays/a
