ACS discovers two distant Type Ia supernovae

Big Bang 10 billion years ago 5 billion years ago Today

Vulcano 2006
Dark Matter sector

The presence of Dark Matter components has been revealed since 1933 by Zwicky as a lack in the mass content of galaxy clusters. The most peculiar effect of Dark Matter is the discover of a non-decaying velocity of rotation curves of galaxies.
Dark matter differences in clusters and galaxies

An important difference between the distribution of dark matter in galaxies and clusters is that whereas dark matter seems to increase with distance in galaxies [M33_Roy D.P. physics/0007025], it is just the opposite situation in clusters. Thanks to gravitational lensing effects, it is possible to estimate that the most of dark matter in clusters is concentrated in the central regions (0.2-0.4 Mpc).

![Graph showing the effective magnitude (m_B) vs. magnitude residual (mag residual) for supernovae data. The graph includes data from Calan/Tololo (Hamuy et al., A.J. 1996) and shows different cosmological models represented by blue and cyan curves. The models include flat (Λ = 0) and non-flat (Λ > 0) universes, with different values for Ω_M and Ω_Λ. The graph highlights the tension between different cosmological models and the observational data.]
Main observational evidences for Dark Energy

After 1998, more and more data have been obtained confirming this result.
Combining SNeIa data with other observations and in particular with data coming from CMBR experiments (COBE, MAXIMA, BOOMERANG, WMAP) we have, up today, a “best fit” (The Concordance Model) universe which is filled with 30% of matter (dark and baryonic) and 70% of dark energy, a component, in principle, different from the standard dark matter. Dark Energy is always characterized by a negative pressure and does not give rise to clustered structures.

The most important consequence of this result is that the universe is in a phase of accelerating expansion

\[ q_0 = \Omega_R + \frac{1}{2} \Omega_M - \Omega_\Lambda + \frac{1}{2} \sum_x (1 + 3w_x) \Omega_x \]

\[ \Omega = \frac{\rho}{\rho_c} \]
\[ \rho_c = \frac{3H^2}{8\pi G} \]

Dark Matter
+ Dark Energy
95%! Vulcano 2006
Dark Matter hints

✔ Neutrino__ Too low mass limit ( $\sum \nu_i m_{\nu_i} < 0.7$ eV ) and relic neutrino density. Shortcomings in forming structures in a considerable time capable of explaining QSO and galaxies at high redshift. Mass requested $\sim (10$ eV$)$. However, neutrino mixing could work for DE giving a dynamical vacuum state [Capolupo, SC, Vitiello 2006].

✔ WIMP (Weakly Interacting Massive Particle)__ Neutralino (neutral supersymmetric fermionic partner of gauge and Higgs bosons [Roszkowsky 1999]). Since WIMPs cluster gravitationally, it should be possible to find some effects of these particles in the Solar System thanks to the nuclear recoil on nucleii targets. Answers from DAMA experiments? [Munoz 2004, Krauss 2004].

✔ MOND _ It is a modification of Newtonian physics which comes out at sufficiently low acceleration $a$ where $F = ma\mu(a/a_0)$

$\mu(x) = x$ when $x \ll 1$ and $\mu(x) = 1$ when $x \gg 1$  Difficulties in explaining galaxy cluster dark matter and in embedding this approach in a general theory of gravity (TeVeS) [Sanders R.H., Megough S., Ann.Rev.Astron.Astrophys.40:263-317,2002; Bekenstein J.D., Phys. Rev D71:069901,2005]

Vulcano 2006
**Dark Energy hints** *(Einstein Lore)*

- Cosmological constant: Introduced by Einstein (1917) to get a static universe, it has been recovered in the last years to interpret the cosmic acceleration evidenced by SNeIa data through the Einstein equations:

\[
R_{ik} - \frac{1}{2}g_{ik}R = \frac{8\pi G}{c^4}T_{ik} + \Lambda g_{ik}
\]

The force law is:

\[
F = -\frac{GM}{R^2} + \frac{\Lambda}{3}R, \quad (R \equiv a)
\]

which shows that the cosmological constant gives rise to a repulsive force which could be responsible for the acceleration of the universe. Since 60's, cosmological constant has been related to vacuum energy of fields. □ Cosmological constant problem (126 orders of magnitude of difference between the theoretical estimate and the observational one) & Coincidence problem (the today observed equivalence, in order of magnitude, of dark energy and dark matter densities).

*Vulcano 2006*
Dynamical dark energy (Quintessence) _ Allows to overshoot the coincidence problem considering a dynamical negative pressure component. The standard scheme is to consider a scalar field Lagrangian.

$$\mathcal{L} = \frac{1}{2} \dot{\phi}^2 - V(\phi),$$

$$\rho \equiv T^0_0 = \frac{1}{2} \dot{\phi}^2 + V(\phi), \quad p \equiv T^\alpha_\alpha = \frac{1}{2} \dot{\phi}^2 - V(\phi)$$

Potentials able to furnish interesting quintessential models:

Resume

Vulcano 2006
In conclusion: The content of the universe is, up today, absolutely unknown for its largest part. The situation is very “DARK” while the observations are extremely good!
Incremental Exploration of the Unknown

More Data Sets

Test $\Lambda$

Test dynamics

More Physics

Test geometry

Test GR

...
The problem could be reversed

We are able to observe and test only baryons and gravity

Dark Energy and Dark Matter as “shortcomings” of GR

The “correct” theory of gravity is derived by matching the largest number of observations

**Accelerating behaviour (DE) and dynamical phenomena (DM) as CURVATURE EFFECTS**

Vulcano 2006
Generalization of the Hilbert-Einstein action to a generic (unknown) theory of gravity

\[ \mathcal{A} = \int d^4x \sqrt{-g} \left[ f(R) + \mathcal{L}_{\text{matter}} \right] \]

\[ f^\prime(R)R_{\alpha\beta} - \frac{1}{2}f(R)g_{\alpha\beta} = f^\prime(R)^{\mu\nu}(g_{\alpha\mu}g_{\beta\nu} - g_{\alpha\beta}g_{\mu\nu}) + \tilde{T}^{\text{matter}}_{\alpha\beta} \]

**Theoretical motivations and features:**

- Quantization on curved space-time needs higher-order invariants corrections to the Hilbert-Einstein Action.
- These corrections are also predicted by several unification schemes as String/M-theory, Kaluza-Klein, etc.
- A generic action is
  \[ A = \int d^4x \sqrt{-g} \left[ F'(R, \Box R, \Box^2 R, \ldots \Box^k R) + \mathcal{L}_m \right] \]
- We can consider only fourth order terms which give the main contributions.
- This scheme allows to obtain an “Einstein” two fluid model in which one component has a geometrical origin

\[
G_{\alpha\beta} = R_{\alpha\beta} - \frac{1}{2} g_{\alpha\beta} R = T^{(\text{curv})}_{\alpha\beta} + T^{(\text{matter})}_{\alpha\beta}
\]

\[
T^{(\text{curv})}_{\alpha\beta} = \frac{1}{f'(R)} \left\{ \frac{1}{2} g_{\alpha\beta} [f(R) - R f'(R)] + f'(R)^\mu\nu (g_{\alpha\mu} g_{\beta\nu} - g_{\alpha\beta} g_{\mu\nu}) \right\}
\]

*Vulcano 2006*

**Conservation Properties of Higher Order Theories**

A key point in the above system is related to the conservation equations. Eddington proved in his book that every higher order correction to the Hilbert-Einstein Lagrangian produces terms that are divergence free: the curvature fluid is conserved on his own and the matter follows the standard conservation equation.

\[
\Box_{\text{curv}} + 3H(\Box_{\text{curv}} + p_{\text{curv}}) = 0
\]
In particular, the $R^n$ Gravity:

Superstring Theory

Generalizations of Einstein gravity at higher dimensions (Lovelock gravity)

Renormalization of the matter stress energy tensor in QFT

Higher Order Theories of Gravity

$$A = \sqrt{\sqrt{g} + c_0 R + c_1 R^2 + c_2 R_{\Box \Box} R^{\Box \Box} + \ldots + L_{\text{mat}} } d^4 x$$

Fourth Order Gravity

$$A = \sqrt{d^4 x \sqrt{-g} \left[ \Box \Box R^n + L_{\text{mat}} \right] }$$

Vulcano 2006
Dark Energy as a curvature effect

It is possible to write a curvature pressure and a curvature energy density in the FRW metric

\[
P_{\text{curv}} = \frac{1}{f'(R)} \left\{ 2 \left( \frac{\dot{a}}{a} \right) \dot{R}f''(R) + \ddot{R}f''(R) + \dot{R}^2 f''(R) - \frac{1}{2} \dot{f}(R) - Rf'(R) \right\}
\]

\[
\rho_{\text{curv}} = \frac{1}{f''(R)} \left\{ \frac{1}{2} \left[ f(R) - Rf'(R) \right] - 3 \left( \frac{a}{\dot{a}} \right) \dot{R}f''(R) \right\}
\]

\[w_{\text{curv}} = -1 + \frac{\ddot{R}f''(R) + \dot{R} \left( Rf'''(R) - Hf''(R) \right)}{\frac{1}{2} \left[ f(R) - Rf'(R) \right] - 3H \dot{R}f''(R)}\]

As a simple choice, we assume a power law function for \( f(R) \) and for the scale factor \( a(t) \)

\[f(R) = f_0 R^n, \quad a(t) = a_0 \left( \frac{t}{t_0} \right)^\alpha\]
The power law $f(R)$ function is interesting since each analytical Lagrangian in R can be locally approximated by a Taylor polynomial expansion. The power law of the scale factor is coherent with the cases of dominant matter and radiation in universe dynamics ($\alpha > 1$ implies accelerating expansion).

(Vacuum case) Solutions for

$$\alpha = \frac{2n^2 - 3n + 1}{2 - n}$$
Matching with data

SNeIa data [SC, Carloni, Cardone, Troisi 2003]

The test with the SNeIa data has been done considering the so called “distance modulus”

\[ \mu(z) = 5 \log \frac{c}{H_0} d_L(z) + 25 \]

comparing its theoretical estimate with the observed one.

The luminosity distance \( d_L(z) \) is defined in relation to the considered cosmological model. In our case, it is

\[ d_L(z, H_0, n) = \frac{c}{H_0} \frac{\alpha}{\alpha - 1} (1 + z) \left[ (1 + z)^{\alpha - 1} - 1 \right] \]

The analysis is performed minimizing the

\[ \chi^2(H_0, n) = \sum_i \frac{[\mu_i^{\text{theor}}(z_i, H_0, n) - \mu_i^{\text{obs}}]^2}{\sigma_{\mu_0,i}^2 + \sigma_{mz,i}^2} \]

Vulcano 2006
f(R) solutions fitted against SNeIa

Very promising results! We have used recent GOODS survey
**The Age test**

The age of the universe can be theoretically calculated if one is capable of furnishing the Hubble parameter. We have:

\[ t = \left( \frac{-2n^2 + 3n - 1}{n - 2} \right) H^{-1} \]

For the experimental value, we have considered both data coming from globular cluster observations and WMAP measurements of CMBR (this last estimate is very precise 13.7 ± 0.02 Gyr) [SC, Cardone, Troisi 2005]

**Result** A fourth order theory \( f(R) = f_0 R^n \) is able to fit SNeIa data and WMAP age prediction with

<table>

</tr>
</tbody>
</table>

\( f(R) \) theories, with small corrections to Einstein Gravity, seem in good agreement with DARK ENERGY, in particular for \(1.366 < n < 1.376\)

*Vulcano 2006*
From field equations
\[ \rho_m = \Omega_{M,0} \rho_{\text{crit}} a^{-3} \]

\[ \frac{dH}{dt} = - \frac{1}{2f'(R)} \left\{ 3H_0^2 \Omega_{M,0}(1 + z)^3 + f''(R) \dot{R} + \left[ f'''(R) \ddot{R} - Hf''(R) \right] \dot{R} \right\} \]

**Fourth order equation for \( a(t) \)**

Considering the relation between \( R \) and \( H \) (FRW-metric) and changing time variable \( t \) with redshift \( z \), we get a **third order diff. eq. for \( f(R(z)) \)**

\[ R = -6 \left[ 2H^2 - (1 + z)H \frac{dH}{dz} \right] \]

\[ \mathcal{H}_3(z) \frac{d^3 f}{dz^3} + \mathcal{H}_2(z) \frac{d^2 f}{dz^2} + \mathcal{H}_1(z) \frac{df}{dz} = -3H_0^2 \Omega_{M,0}(1 + z)^3 \]

with \( H \) functions defined in term of \( R(H(z),z) \) and its \( z \) derivatives

✓ \( H(z) \) can be inferred from observations or by phenomenological approaches. The goal is numerically finding \( f(z) \) and then back tranforming this thanks to \( z = z(R) \) in \( f(R) \)

**Q-essence,** \( f(z) \) → \( f(R) \) (\( l_1, l_2, l_3, l_4 \)) = (2.6693, 0.5950, 0.0719, -3.0099)

**Chaplygin,** \( \ln(-f) = l_1 \ln(-R)^{l_2} [1 + \ln(-R)]^{l_3} + l_4 \)

\( (l_1, l_2, l_3, l_4) = (1.9814, 0.5558, 0.2665, -2.5337) \)

**Vulcano 2006**
Can $f(R)$-theories reproduce also Dark Matter dynamics?

Main research interests:
1) Galactic dynamics (rotation curves of spiral galaxies)
2) DM in the Ellipticals
3) Galaxy cluster dynamics

The problem: we search for $f(R)$-solutions capable of fitting consistently the data. A nice feature is that the same $f(R)$ – theory could work for Dark Energy (very large scales) and Dark Matter (small and clustered scales).

Vulcano 2006
DM in the galaxies as a curvature effect

Theoretical issues

Spiral galaxies are ideal candidates to test DM models. In particular, LSB galaxies are DM-dominated so that fitting their rotation curves WITHOUT DM is a good test for any alternative gravity theory.

A further test is trying to fit Milky Way rotation curve WITHOUT DM. In this case, the approach could be problematic.

In general, is it possible to define an effective dark matter halo induced by curvature effects?

What about baryonic Tully-Fischer relation without DM?
**DM as a Curvature effect:**

- Let us consider again: \[ f(R) = f_0 R^n \]

✓ In the low energy limit, the spacetime metric can be written as

\[
ds^2 = A(r) dt^2 \Box B(r) dr^2 \Box r^2 d\Omega^2
\]

✓ A physically motivated hypothesis is

\[
A(r) = \frac{1}{B(r)} = 1 + \frac{2 \Box (r)}{c^2}
\]

✓ An exact solution is

\[
\Phi(r) = -\frac{Gm}{2r} \left[ 1 + \left( \frac{r}{r_c} \right)^\beta \right]
\]

with

\[
\beta = \frac{12n^2 - 7n - 1 - \sqrt{36n^4 + 12n^3 - 83n^2 + 50n + 1}}{6n^2 + 4n - 2}
\]

✓ For \( n=1 \), \( \Box = 0 \). The approach is consistent with GR!
The pointlike rotation curve is

\[ v_c^2(r) = \frac{GM}{r} \left[ 1 + (1 - \beta) \left( \frac{r}{r_c} \right)^\beta \right] \]

The galaxy can be modeled considering a thin disk and a bulge component.

The potential can be splitted in a Newtonian and a correction part

\[ \Phi(r) = \Phi_N(r) + \Phi_c(r) = \frac{GM(r)}{r} + \Phi_c(r) \]

Integration can be performed considering a spherical symmetry for the bulge and a cylindrical symmetry for the disk.

\[ \Phi_i(\tilde{r}, z) = \int_0^{\tilde{r}} d\tilde{r} \int_0^{2\pi} d\phi \int_{-z}^z dz' \Phi(\tilde{r}', z') \tilde{r}^i \]

\[ \Phi_i = \begin{cases} 1 & i = N \\ \Phi(n) & i = c \end{cases} \]

The rotation curve is given by

\[ v_{circ}^2(\tilde{r}) = \tilde{r} \left. \frac{\partial \Phi_i}{\partial \tilde{r}} \right|_{z=0} \]

No DARK component has been used!

Vulcano 2006
**Milky Way data fit**

*Result*

The upper points are affected by systematic errors as discussed in Pont et al. 1997

*Also in this case, NO Dark Matter is needed*

*Vulcano 2006*
At this point, it is worth wondering whether a link can be found between fourth order gravity and the standard approach, based on effective dark matter haloes, since both approaches fit equally well the data.

Considering
\[ v_c^2(r) = v_{c,N}^2(r) + v_{c,corr}^2(r) \]
and
\[ v_c^2(r) = v_{c,disk}^2(r) + v_{c,DM}^2(r) \]
being
\[ v_{c,DM}^2(r) = GM_{DM}(r)/r \]

Equating the two expressions, we get
\[ M_{DM}(\eta) = 2^{\beta-5}\eta_c^{-\beta}\pi(1-\beta)\Sigma_0 R_d^2 \eta^{\frac{\beta+1}{2}} I_0(\eta,\beta) \]
where
\[ \eta = r/R_d, \Sigma_0 = \gamma I_0 \]
and
\[ I_0(\eta,\beta) = \int_0^\infty F_0(\eta,\eta',\beta)k^{3-\beta}\eta'^{\frac{\beta-1}{2}}e^{-\eta'}d\eta' \]

this means that the mass profile of an effective spherically symmetric DM halo, which provides corrected disk rotation curves, can be reproduced.

For \[ \beta = 0.58 \pm 0.15 \] \textbf{Burkert models are exactly reproduced!} [Burkert 1995] Vulcano 2006
From Virial theorem: \[ V_{\text{vir}} = GM_{\text{vir}}/R_{\text{vir}} \]

\[ M_d = \frac{(3/4\pi\delta_{\text{th}}\Omega_m \rho_{\text{crit}})}{2^\beta - 6(1 - \beta)G^{5-\beta/4}} \frac{R_d^{1+\beta}}{\eta_c} \frac{V_{\text{vir}}^{5-\beta}}{I_0(V_{\text{vir}}, \beta)} \]

Where \( M_d \propto V_{\text{vir}}^\alpha \) is the disk mass. For \( \beta = 0.58 \pm 0.15 \)

**empirical baryonic Tully-Fisher relation is reproduced!**

[SC, Cardone, Troisi 2006]
In summary: Dark Matter dynamics can be reproduced by f(R)-gravity

Results:
1) Galactic dynamics (rotation curves of LSB spiral galaxies)
2) Milky Way rotation curves
3) Burkert haloes
4) Tully-Fisher relation

Further issues: HSB galaxies, Elliptical galaxies, Clusters.
A nice feature could be that the same f(R) – theory works for Dark Energy (very large scales, unclustered) and Dark Matter (small and medium scales, clustered structures)
Summarizing the results

- Good agreement also with lookback time methods (time measurements) [SC, Cardone, Funaro, Andreon (2004)]

- Luminosity distance in f(R) [SC, Cardone, Troisi (2004)]

- f(R)- dynamical systems and stability analysis [Carloni, SC, Dunsby, Troisi (2005)]

- Rotation curves of LSB galaxies [SC, Cardone, Troisi (2006)]

- Baryonic Tully-Fisher, Burkert haloes [SC, Cardone, Troisi (2006)]

Vulcano 2006
Perspectives:

- Matching other DE models
- Jordan Frame and Einstein Frame
- Systematic studies of rotation curves of other galaxies
- Galaxy cluster dynamics (virial theorem, SZE, etc.)
- Luminosity profiles of galaxies in f(R).
- Faber-Jackson & Tully-Fisher

Weak Fields, GW and Static Fields

- Systematic studies of PPN formalism
- Relativistic Experimental Tests in f(R)
- Gravitational waves and lensing
- Birkhoff ‘s Theorem in f (R)-gravity

WORK in PROGRESS! (suggestions are welcome!)

Vulcano 2006
Ending with a joke: Dark Matter in the Lab!

...and if, after spending all this money, are there no further particles to discover?
