The evolution of the Universe

Key:

	photon		star
W, Z	bosons		meson
q	quark		baryon
e	electron		ion
e	positron		atom
v	neutrino		galaxy
			black hole

In order to understand the deepest nature of the matter we have to:

create the initial conditions of the Universe

create who is carrying the information

create the relevant particles

Particle Factories: the accelerators

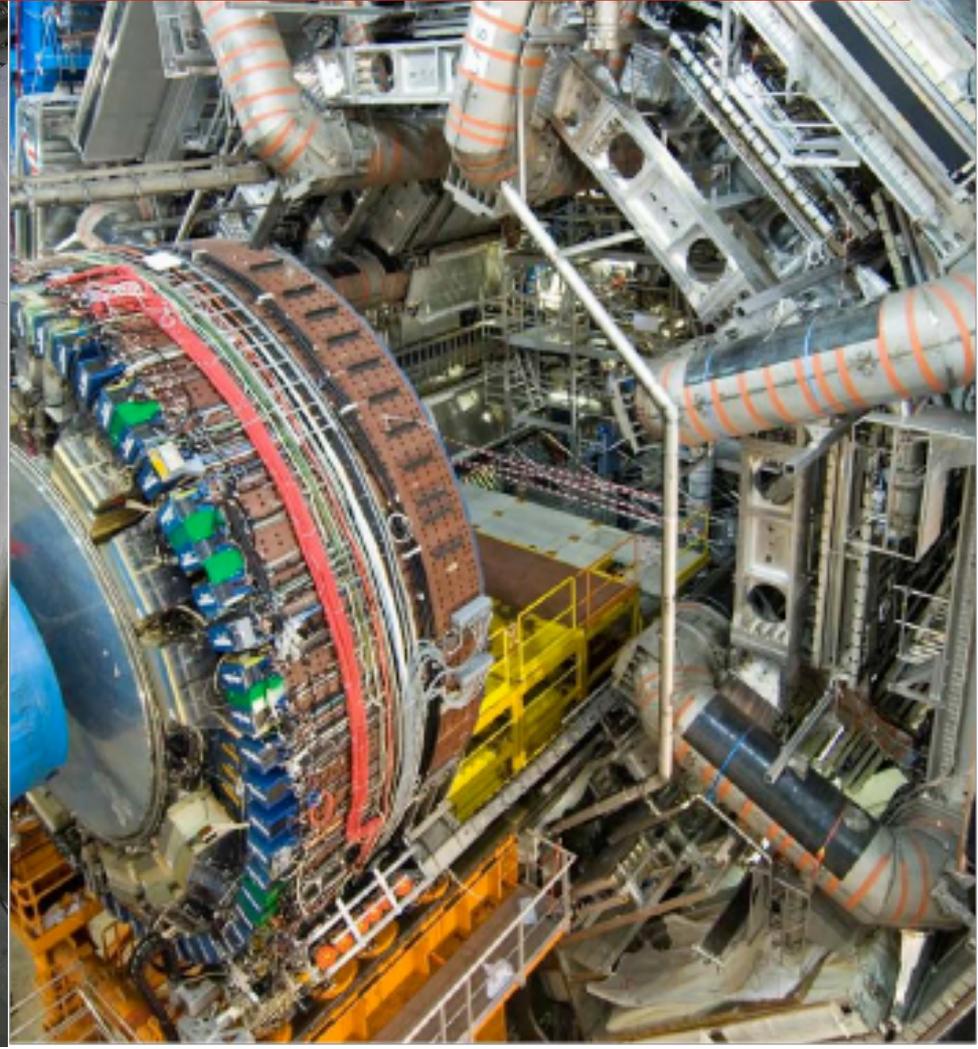

Colliders

Overall view of the LHC experiments.

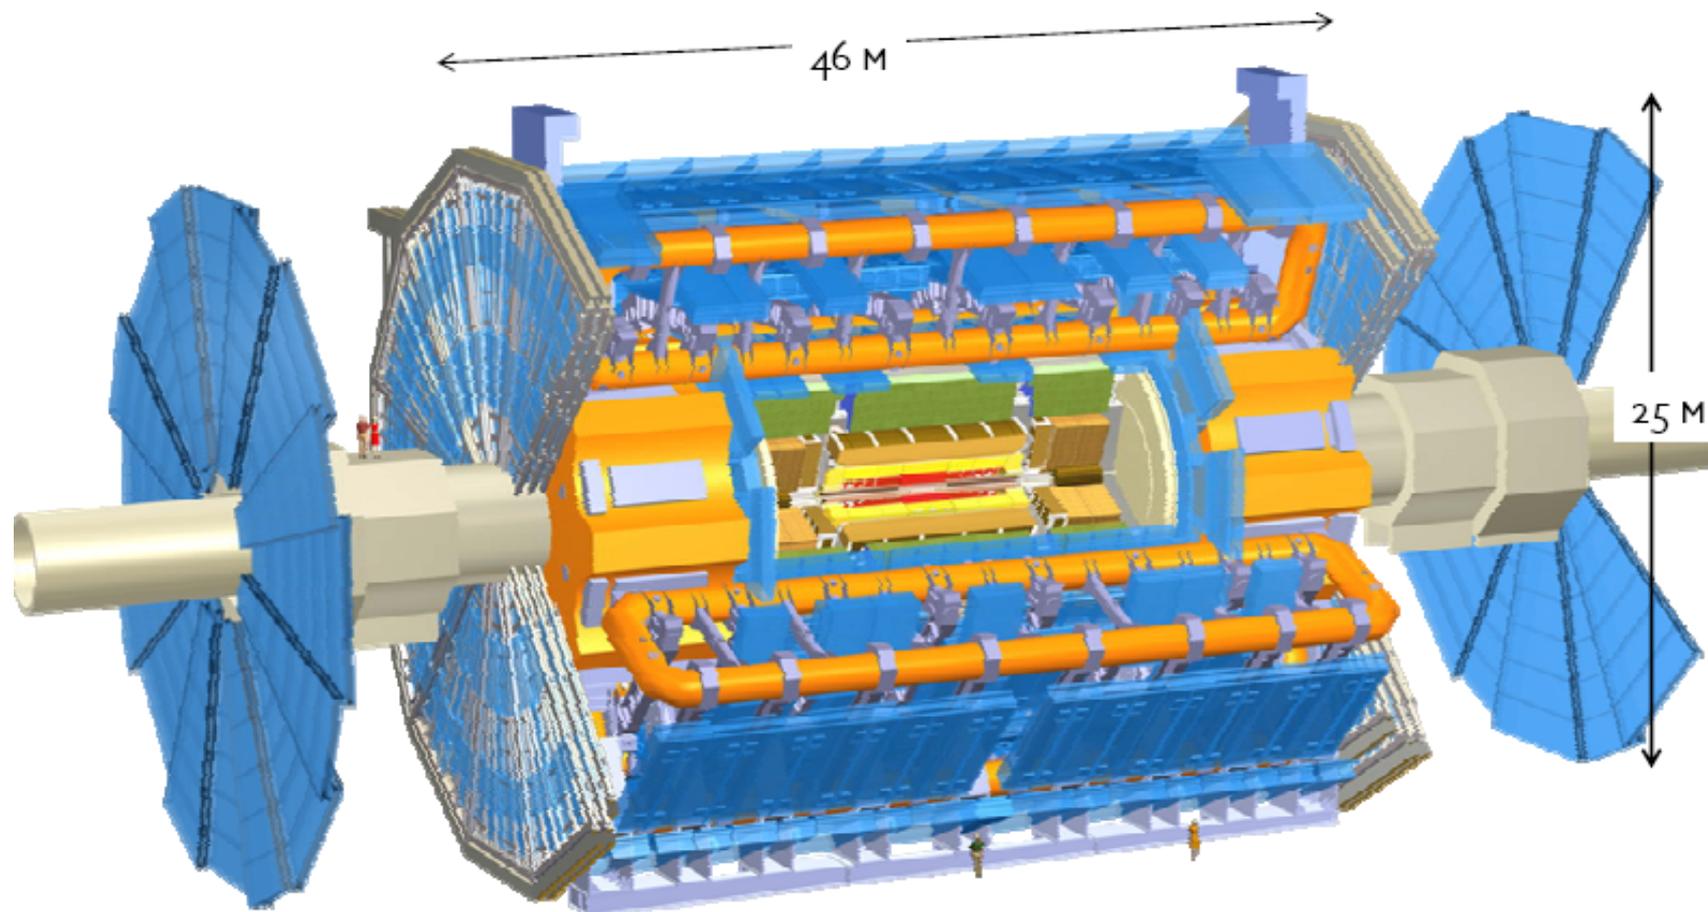

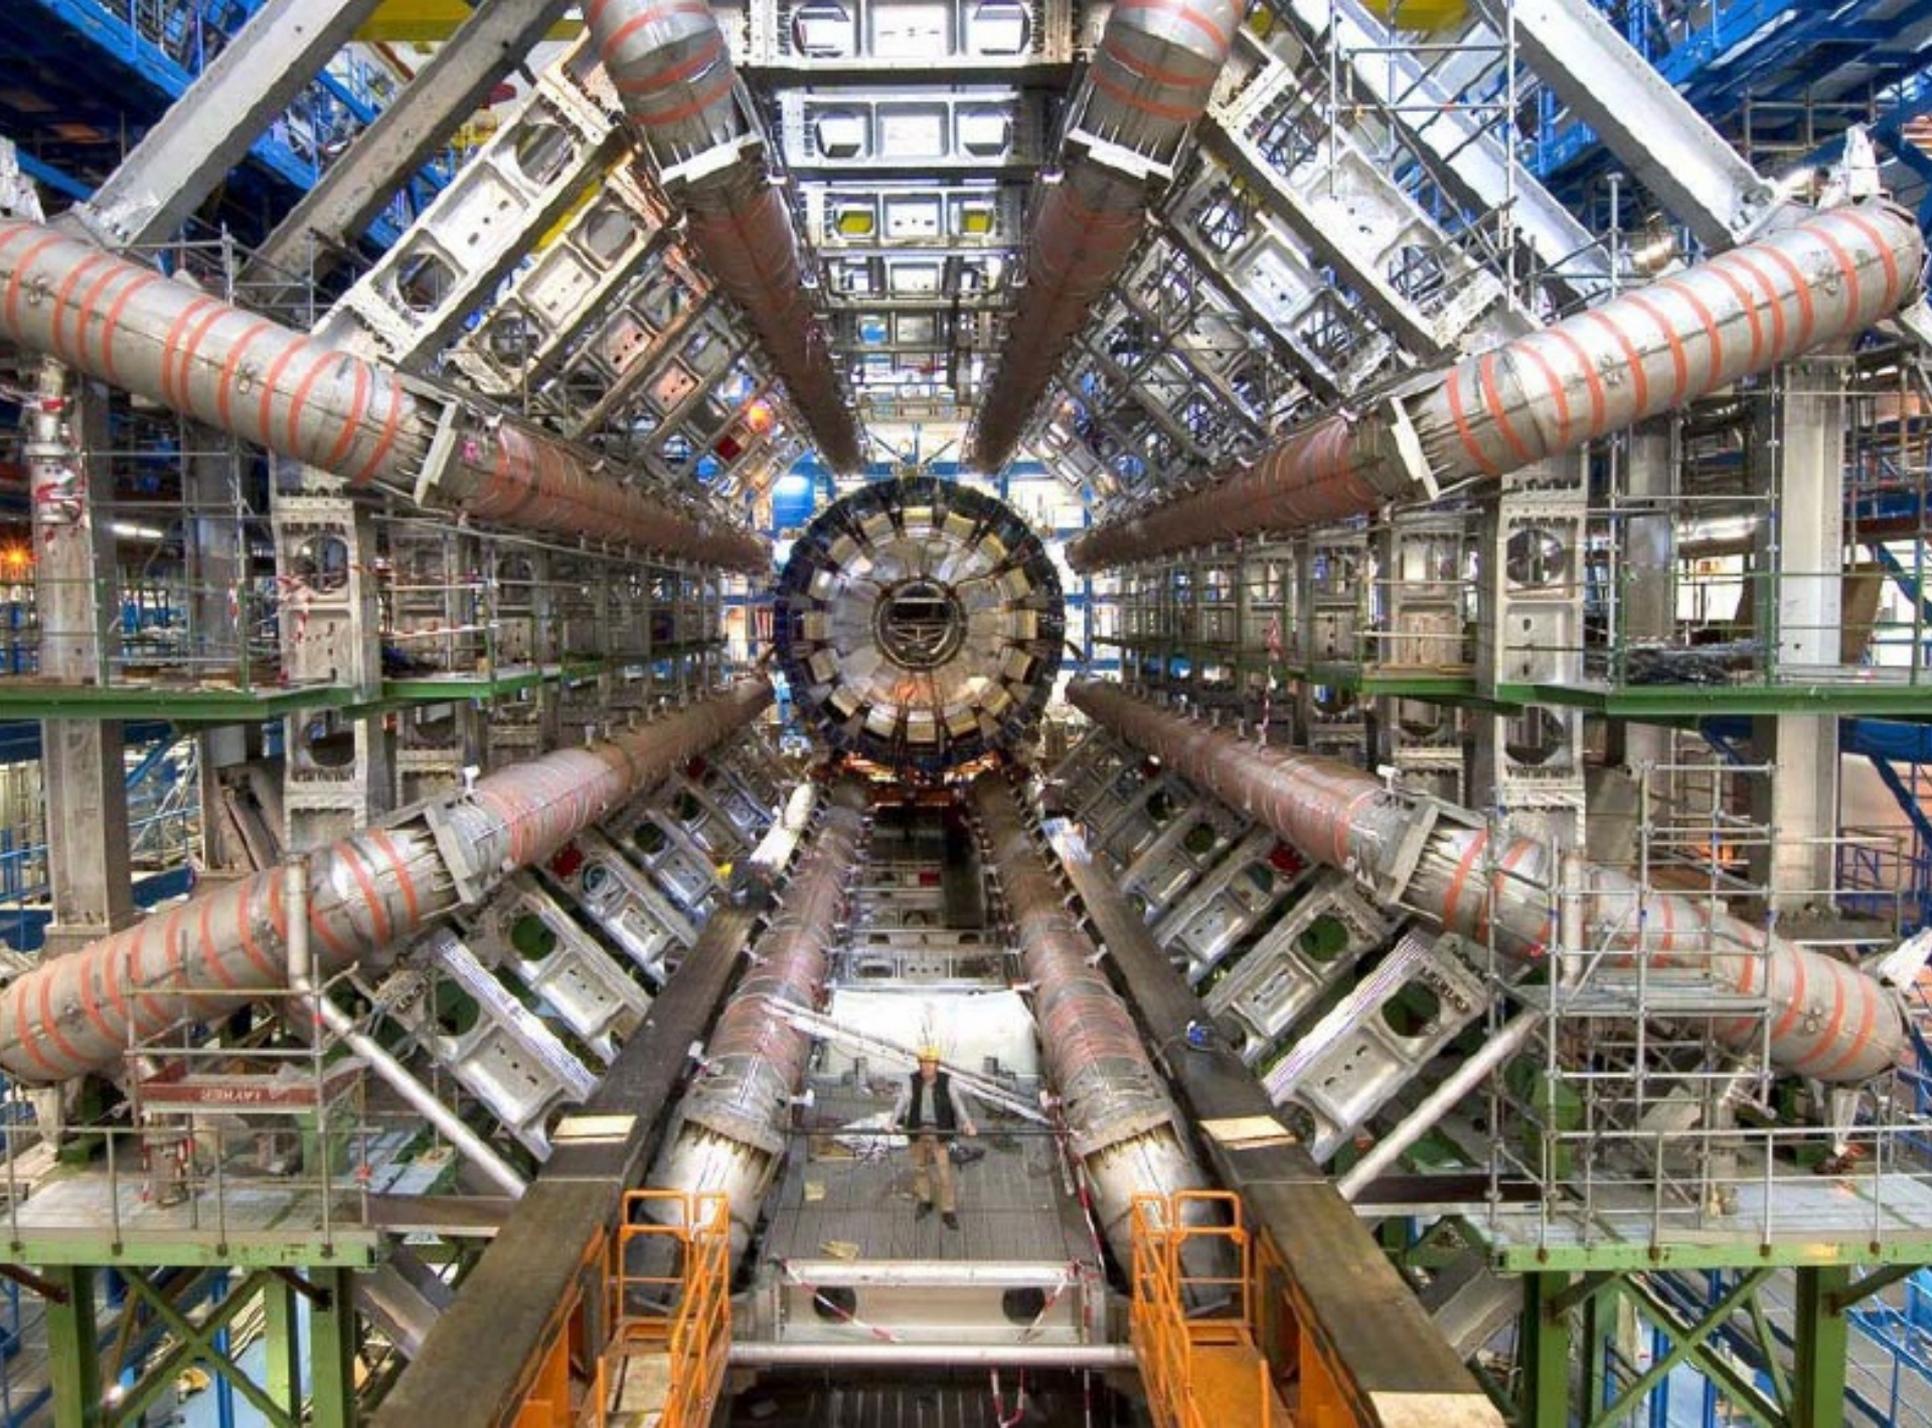

E540 - V10/09/97

- 4 gigantic caverns host 4 huge detectors
- center of mass energy of 14 TeV, never reached before
- beam intensity orders of magnitude higher than before
- almost 40.000 ton of material at 1.9 K, a temperature lower than the cosmic background

1 The cosmos goes through a superfast "inflation," expanding from the size of an atom to that of a grapefruit in a tiny fraction of a second

2 Post-inflation, the universe is a seething, hot soup of electrons, quarks and other particles

3 A rapidly cooling cosmos permits quarks to clump into protons and neutrons

4 Still too hot to form into atoms, charged electrons and protons prevent light from shining; the universe is a superhot fog

5 Electrons combine with protons and neutrons to form atoms, mostly hydrogen and helium. Light can finally shine

6 Gravity makes hydrogen and helium gas coalesce to form the giant clouds that will become galaxies; smaller clumps of gas collapse to form the first stars

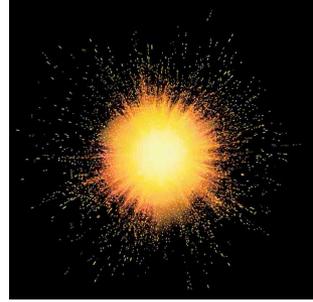

7 As galaxies cluster together under gravity, the first stars die and spew heavy elements into space; these will eventually form into new stars and planets

NOTE: The numbers in cosmology are so great and the numbers in subatomic physics are so small that it is often necessary to express them in exponential form. Ten multiplied by itself, or 100, is written as 10^2 . One thousand is written as 10^3 . Similarly, one-tenth is 10^{-1} , and one-hundredth is 10^{-2} .

TIME Graphic by Ed Gabel

A Mini-Bang in the lab

- We need a small system so that it can be accelerated to ultrarelativistic speed (99.9% c)
- That system (i.e. a chunk of matter and not just a single particle) must follow simple rules of thermodynamics and form a new state of matter in a particular phase
- We can use heavy ions (e.g. Pb). They are tiny ($\sim 10^{-14}$ m) but have a finite volume that can be exposed to pressure and temperature

We will try to force matter, through a phase transition, to a new state of matter called “Quark Gluon Plasma”

We need Heavy Ions

A simulated collision in Alice

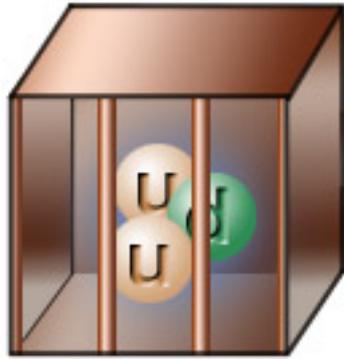

Up to 10^{-37} - 10^{-5} s from the Big Bang the Universe was formed by a “soup” of quarks and gluons ... the Quark Gluon Plasma (QGP)

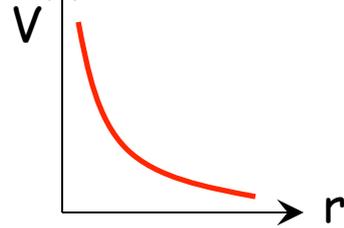

- Why to study the QGP?
- Which are the main features of the QGP?
- Is it possible to have such a system in laboratory?
 - $T_{\text{QGP}} = 2000$ billions K
 - $T_{\text{SUN}} = 15$ millions K

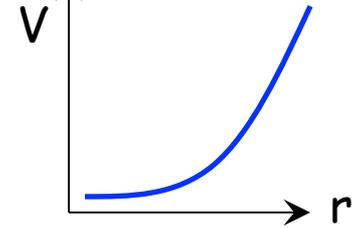

Asimptotic freedom → Confinement

$$V_{\text{Coulomb}} \propto \frac{q_1 q_2}{r}$$

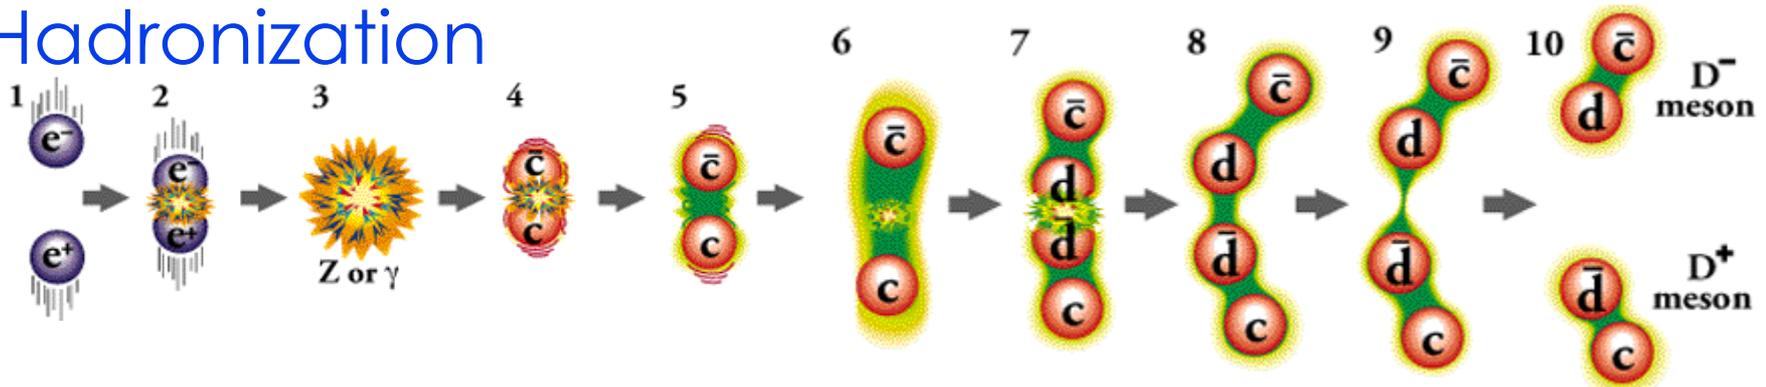

$$V_{\text{QCD}} \propto e^{k \cdot r}$$

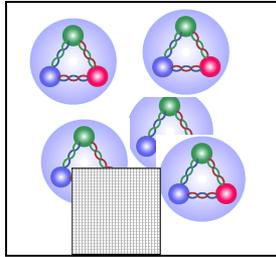

Separating interacting quark, a tension (energy) able to create new particles is formed (1000 MeV / fm)

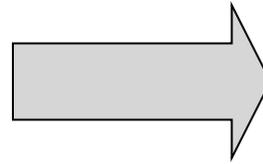

Hadronization

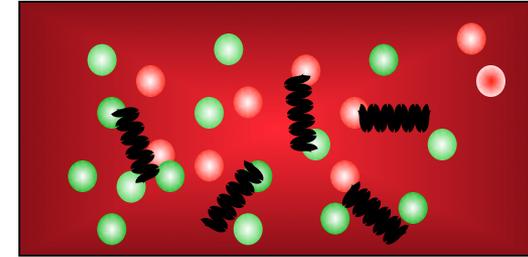

We need to create a system with high energy density (particles at infinitesimal distance) in order to have negligible strong interactions

QCD Asymptotic Freedom (1973)

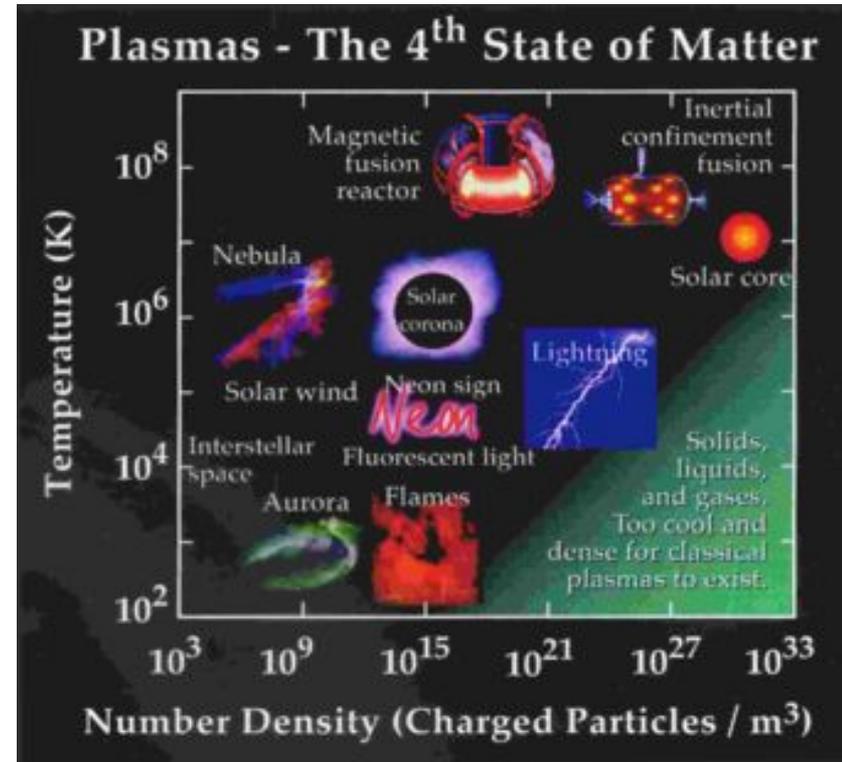

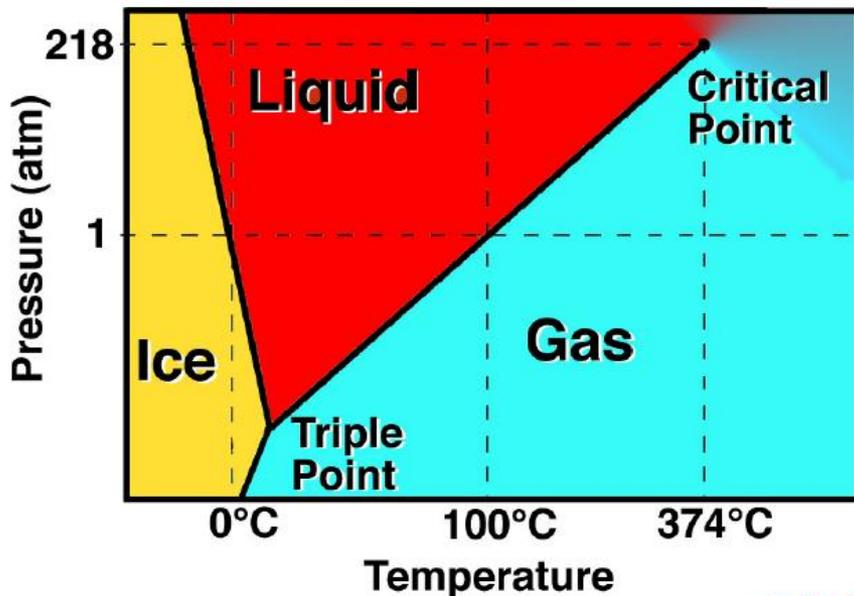

“Before [QCD] we could not go back further than 200,000 years after the Big Bang. Today...since QCD simplifies at high energy, we can extrapolate to very early times when nucleons melted...to form a quark-gluon plasma.”

David Gross, Nobel Lecture (RMP 05)

Phase transition in cosmological theories of the primordial Universe

Equation state of QCD

Partonic energy loss

Chemical composition

Global observables summary

The Early Universe behaved as a perfect fluid

Something less interesting ... at least for you

- Energy density $> 50 \text{ GeV/fm}^3$
- Freeze-out volume $\sim 300 \text{ fm}^3$
- Time scale until decoupling $10 \text{ fm}/c$
- Elliptic flow as expected from hydro-dynamical calculations
- Initial state saturation effects smaller than expected

Can a Black Hole be produced at the LHC?

Black Holes evolution and decay

- Mini black holes produced at LHC would be light and tiny compared to cosmic black holes (\sim TeV versus \sim 3 Solar masses)
- This means they would be extremely hot ($T \sim 100$ GeV) and evaporate almost instantaneously, mainly via Hawking radiation
- \rightarrow cosmic BH 10^{19} GeV \rightarrow LHC energy $\sim 10^4$ GeV

- Typical decay signature:
~6 ptc for each decay emitted spherically

75% quarks and gluons

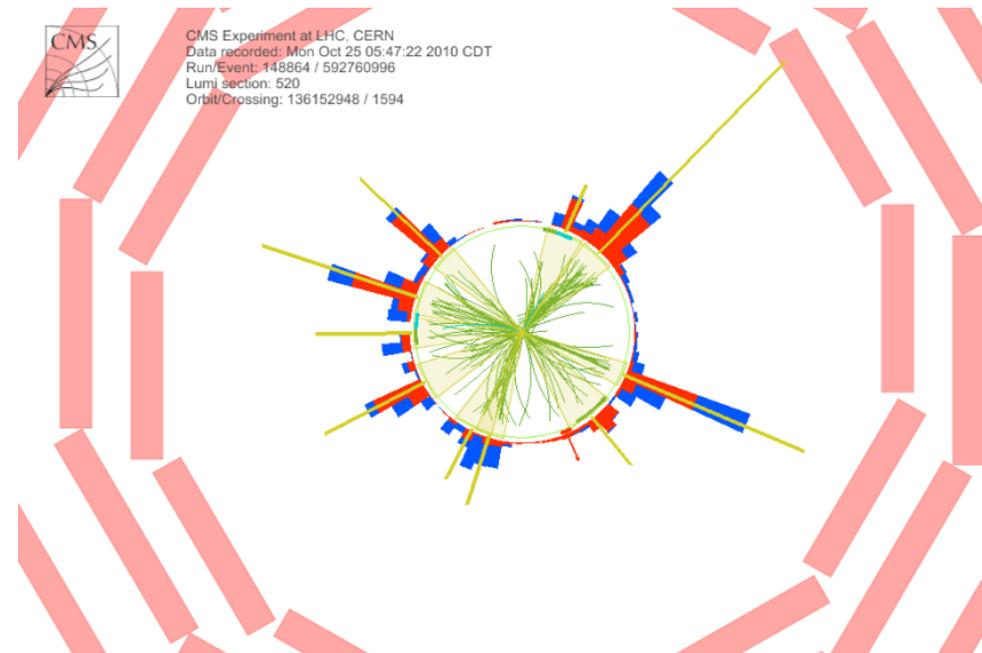

10% charged leptons

5% neutrinos

5% of photons or W/Z boson

new ptc around 100 GeV

*BH event
simulated by CMS*

Conclusions

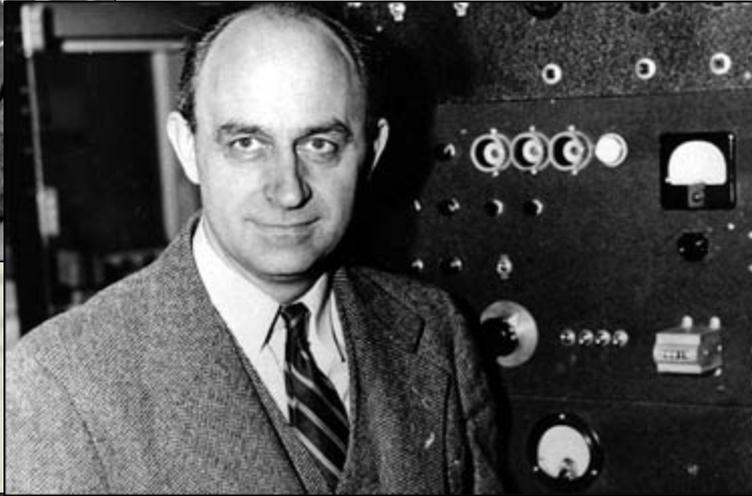

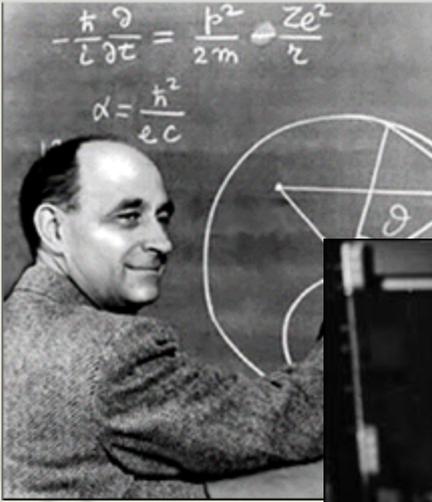

Alice and the LHC are operating wonderfully unveiling the first secrets of the Early Universe

A new and unique era for the exploration of the matter just started. The connections with other branches of physics are incredibly high and intriguing
