

REVIEW OF CRYSTAL CALORIMETERS

V.B.Golubev,
Budker Institute of Nuclear Physics,
Novosibirsk, Russia

Crystal Ball Detector

The first large-scale crystal calorimeter in high energy physics was the NaI(Tl) calorimeter of the Crystal Ball detector. It showed high discovery potential of the crystal calorimeters.

Crystal Ball NaI(Tl) Calorimeter

6 - 79

Number of crystals 672
 Inner radius 25.4 cm
 Outer radius 66.0 cm
 Thickness $16 X_0$
 Solid angle coverage 93%
 Photodetector PMT
 Noise 0.05 MeV
 Dynamic range 10^4

$$\frac{\sigma_E}{E} = \frac{2.8\%}{\sqrt[4]{E(\text{GeV})}}$$

Inclusive photon spectrum at $\psi(2S)$ resonance

Crystal calorimeter benefits

- High efficiencies for electrons and photons
- Best energy resolution and good position and angular resolution for photons and electrons
- High linearity and wide dynamic range
- Radiation hardness
- Reliability and simplicity of maintenance
- Compact size

Energy resolution and line shape

- Light collection and crystal light output nonuniformities
- Fluctuations of the shower energy losses
- Photoelectron statistics
- Inaccuracy of the calibration of individual channels
- Electronics noise and instabilities

Commonly used parameterizations of the calorimeter line shape:

Crystal Ball function

$$C(x) = \begin{cases} N \exp\left[-\frac{(x-x_0)^r}{r\sigma^r}\right] & \text{for } x > x_0 - \alpha\sigma \\ N \frac{(n/\alpha)^n e^{-\frac{\alpha^r}{r}}}{[(x-x_0)/\sigma + n/\alpha - \alpha]^n} & \text{for } x \leq x_0 - \alpha\sigma \end{cases}$$

N – norm. factor
 x_0 – peak position
 σ – Gaussian width
 α – joint parameter

Logarithmic Gaussian (Novosibirsk function)

$$W(x) = N \exp\left[-\frac{1}{2} \left(\frac{\log[1 + \tau(x-x_0) \frac{\sinh[\tau\sqrt{\log 4}]]}{\sigma\tau\sqrt{\log 4}} \right)^2 + \tau^2 \right]$$

N – norm. factor
 x_0 – peak position
 σ – FWHM/2.35
 τ – peak asymmetry

BABAR calorimeter line shape.
Fit – Crystal Ball function

SND detector

SND detector; 1 – Be vacuum chamber, 2 – tracking system, 3 – aerogel Cherenkov counters, 4 – NaI(Tl) scintillation counters, 5 – vacuum phototriodes, 6 – iron absorber, 7,8 – muon system.

SND NaI(Tl) calorimeter

SND calorimeter geometry

SND calorimeter segment

Number of crystals - 1632, thickness – $13.5 X_0$, mass – 3.5 tons
Photodetectors – vacuum phototriodes with photocathode quantum efficiency of ~15% and gain ~10.

Three-layer structure allows high quality e/π separation by using measurement of the shower energy deposition longitudinal profile

SND calorimeter resolution

Crystal calibration – using cosmic muons (precalibration) and Bhabha scattering events (final calibration)

Future plans – the use of the calorimeter for the time of flight measurement for selection of $e^+e^- \rightarrow n\bar{n}$ events. The resolution of 2ns for energy deposition of 70 MeV was achieved in the test with an SND calorimeter crystal (to be presented at INSTR08 poster session)

L3 BGO calorimeter

Number of crystals:
Barrel – 7680
Endcaps – 2×1527
Thickness – $22X_0$
Photodetector – Si PD

L3 detector at LEP 1980-2000

L3 calorimeter calibration

Proton RFQ accelerator-based calibration system

RFQ accelerator produces 1.85 MeV H^- beam. After focusing and steering it is neutralized and directed through the detector magnetic field to Li target inside the detector.

Resonant proton radiative capture reaction ($\sigma=5\text{mb}$) produces calibration photons:
 $p+{}^7\text{Li} \rightarrow {}^8\text{Be} + \gamma$ (17.6 MeV)

Calibration accuracy – 0.5%

L3 calorimeter energy resolution

Contribution	Intrinsic	Temperature	Calibration	Overall
Barrel	0.8%	0.5%	0.5%	1.07%
Endcap	0.6%	0.5%	0.4%	0.88%

L3 calorimeter discovery potential

Study of the process
 $e^+e^- \rightarrow \nu\bar{\nu}(\gamma)$
Determination of the number
of light neutrinos

KTeV detector

KTeV Csl calorimeter

- o Calorimeter size 1.9x1.9 m²
- o Number of crystals 3100
- o Thickness 27 X₀
- o Crystal size 2.5x2.5x50 cm³ (central part), 5.0x5.0x50 cm³ outer part
- o Photodetector – PMT
- o Calibration – electrons from K_{e3} decays

$$\frac{\sigma_E}{E} = \frac{2\%}{\sqrt{E(\text{GeV})}} \oplus 0.45\%$$

Nonlinearity (3 – 75 GeV) 0.4%

Spacial resolution for photons ~1 mm

CLEO-c detector

CLEO-c CsI(Tl) calorimeter

- Number of crystals 7784:
Barrel – 6144
Endcaps – 2×820
- Crystal size – $5 \times 5 \times 30$ cm³
- Thickness – $16.2 X_0$
- Inner radius – 1.02 m
- Barrel length – 3.26 m
- Total CsI(Tl) mass – 27000 kg
- Solid angle coverage – 95%
- Photodetector Si photodiode (4 per crystal)
- Material in front of the barrel part – $0.18 X_0$

- installed 1990
- *Improved endcap*
- photon det.
- electron ID
- Trigger
- Luminosity
- π^0 , η
- missing E

CLEO calorimeter performance

BABAR Detector

BABAR CsI(Tl) Calorimeter

Number of crystals – 6580,
 Thickness – $16 \div 17.5 X_0$
 Inner radius – 0.92 m
 Length – 2.9 m
 Solid angle coverage 90% (in cms)

$$\frac{\sigma_E}{E} = \frac{(2.3 \pm 0.03 \pm 0.3)\%}{\sqrt{E(\text{GeV})}} \oplus (1.35 \pm 0.08 \pm 0.2)\%$$

$$\theta = 5.5 \pm 0.04 \text{ mrad}$$

$$\sqrt{s} = 10.58 \text{ GeV}$$

BABAR Calorimeter Calibration

- Liquid radioactive source based on the reaction: $^{19}\text{F}(n,\alpha)^{16}\text{N}$; $^{16}\text{N} (7s) \rightarrow ^{16}\text{O}^* \rightarrow ^{16}\text{O} + \gamma (6.13 \text{ MeV})$;
- Bhabha scattering (2.5 – 8 GeV), 200 direct hits per crystal, 0.35% statistical and 1% systematic error;
- Additional corrections using π^0 decays, $e^+e^- \rightarrow e^+e^-\gamma$ and $\mu^+\mu^- \gamma$ reactions

Neutron generator based on deuterium-tritium fusion reaction.

Generates up to 10^9 14 MeV n/s, when high voltage on.

Activates Fluorinert FC77 liquid
Counting rate 40 photons per crystal per second

Calibration accuracy $\sim 0.25\%$ for 15-30 minute run

BABAR Calorimeter Performance

Liquid source calibration spectrum in one crystal.
Fit – 3 Gaussians (6.13 MeV peak + 2 escape peaks) and parameterized background.
Resolution – $\sigma=0.3$ MeV

π^0 peak in $\gamma\gamma$ invariant mass spectrum for $E_\pi > 300\text{MeV}$

Relative drop in light yield versus time

CMS Detector

CMS calorimeter requirements

One of the main goals of the CMS detector is a discovery of the Higgs boson. For the $M_H = 100\div 150\text{GeV}$ the golden decay mode is

$H \rightarrow \gamma\gamma$.

The CMS EM calorimeter design resolution:

$$\frac{\sigma_E}{E(\text{GeV})} = \frac{a}{\sqrt{E}} \oplus \frac{b}{E} \oplus c,$$

where $a = 2.7\%$, $b = 200\text{ MeV}$, $c = 0.5\%$

Radiation doses at high LHC luminosities:
Barrel center – 0.15Gy/h , Endcap – 15Gy/h

Typical loss of transparency in PbWO_4 is 3% at 0.15 Gy/s – requires precision real time monitoring of the crystal optical properties.

Expected total γ -radiation doses for 10-year running at highest luminosity are 10^4 Gy in the barrel and $\sim 10^6\text{ Gy}$ in endcaps. Expected neutron fluence is 10^{13} n/cm^2

New crystals for HEP calorimetry and ILC calorimeter proposal

Cube: 1.7 X 1.7 x 1.7 cm ($1.5 X_0$)
Bar: 2.5 x 2.5 x 20 cm ($18 X_0$)

R.Y. Zhu, 2005 ALCPG & ILC
Workshops Snowmass, USA[1]

LSO – $\text{Lu}_2\text{SiO}_5(\text{Ce})$

LYSO – $\text{Lu}_{2(1-x)}\text{Y}_{2x}\text{SiO}_5(\text{Ce})$
 $x=5 - 10\%$

In a last decade the mass production capabilities for LSO and LYSO crystals were established mostly for the medical industry. Their potential applications in HEP were also explored

LSO properties

- Density – 7.40 g/cm³
- Radiation length – 1.14 cm
- Moliere radius – 2.07 cm
- Light yield – 84% of NaI(Tl)
- λ_{max} – 420 nm
- Decay time – 42 ns
- Small temperature dependence of the light yield

0.511 MeV ^{22}Na spectra from long crystal samples
Photodetector – 2 Hamamatsu 5x5 mm² APDs per crystal.
Light output – 2000 p.e./MeV
Noise – 35 keV

LSO (LYSO) radiation hardness

The tests of radiation hardness of L(Y)SO crystals (J.M.Cheng et al., IEEE Trans Nucl Sci. 52 (2002)[2]; P.Kozma and P.Kosma Jr., NIM A539(2005)132[3]) showed that the radiation hardness of LSO crystals is very high.

Complete recovery after 10^5 Gy gamma irradiation takes few days. The radiation hardness of LSO is higher than that of BGO and PWO.

The main problem with the LSO crystal radiation damage could be radiation-induced phosphorescence. The estimated radiation-induced read-out noise is ~ 1 MeV for 100 ns gate and 500 rad/h dose rate [2].

Thus, the LSO and LYSO crystals are good candidates for ILC detector calorimeter. Another possible application is the SuperB detector calorimeter endcaps.

Summary

- In crystal calorimeters the e/γ showers are totally absorbed in sensitive media. This provides the best energy resolution for electrons and photons and also a good spatial resolution.
- Crystal calorimeters have wide dynamic range of up to 10^5 and low energy threshold of few MeV or less.
- Crystal calorimeters are highly reliable and simple in maintenance.
- New high-density scintillation crystals like LSO and LYSO have high light output and transparency, short scintillation decay time and very high radiation hardness. This makes the crystal calorimeters based on these crystals a good choice for future HEP detectors including detector for ILC.
