## INFN/AE-75/4 <br> 10 Aprile 1975

E. Di Salvo: ANALYSIS ON THE $\mathrm{N}^{\star}(1700)$ RESONANCE.

ABSTRACT - We will present some model independent tests to analyze the production mechanism and the decay of the $\mathrm{N}^{\mathrm{*}}(1700)$. Some of them are of general interest.

## INTRODUCTION, -

The $N^{\star}(1700)$ resonance has been studied in several reactions:

$$
\begin{align*}
& \pi^{+} \mathrm{p} \rightarrow \pi^{ \pm}\left(\mathrm{p} \pi^{+} \pi^{-}\right) \\
& \mathrm{K}^{+} \mathrm{p} \rightarrow \mathrm{~K}^{+}\left(\mathrm{p} \pi^{+} \pi^{-}\right)  \tag{1}\\
& \mathrm{p} \mathrm{p} \rightarrow \mathrm{p}\left(\mathrm{p} \pi^{+} \pi^{-}\right) \\
& \overline{\mathrm{p}} \mathrm{p} \rightarrow \overline{\mathrm{p}}\left(\mathrm{p} \pi^{+} \pi^{-}\right) .
\end{align*}
$$

The analyses ${ }^{(1-28)}$ on the experimental data relative to the system suggest $\frac{5}{2}^{+}$as the most likely spin-parity assignement for the $\mathrm{N}^{\star}(1700)$; they give also some indications in favour of diffractive production. Most of the spin-parity tests consist in the study of the angular distributimon for the normal to the $\mathrm{N}^{\star}$ decay plane ${ }^{(29)}$. In other tests one assumes that the $\mathrm{N}^{\star}$ decays totally into $\Delta^{++} \pi^{-}$: however, it is very difficult to show this, because the $N^{\star}$ is very close to the threshold ${ }^{(25)}$ : in the various papers very different decay percentages are given.

Also the diffractive hypothesis, which is often assumed in the tests, should be verified.
Our purpose is to present some model independent tests to be applied to the $\pi^{+} \pi^{-} p$ system, and particularly in the 1700 MeV region. Only some very general hypotheses are formulated and some of the above assumptions on the $\mathrm{N}^{\star}$ could be tested. We also outline that many of the arguments we will present are of general interest.

In section 1 we shall discuss some tests, with their limitations, on the density matrix delemints.

In section 2 we shall write some functions to be used in the fit to the decay angular distributimon, in order to determine the value of the $\mathrm{N}^{\star}$ spin, the matrix elements and the decay parameter to be inserted in the Dalitz plot Analysis. We also indicate a test for $s$-channel and $t$-channel helicity conservation.
2.

In section 3 we discuss the Dalitz plot analysis. We show that it is possible to write a fundtion depending on 7 free parameters, with only a general hypothesis about the background. Also the branching ratios of the $\mathrm{N}^{\boldsymbol{*}}$ decay modes can be determined.

## 1. - TESTS ON THE DENSITY MATRIX ELEMENTS. -

At first, we observe that there are some limitations on the density matrix elements for the diffractively produced resonances ${ }^{(26)}$. For example, in the $N^{*}$ production induced by proton-pro ton collision, we have

$$
\mathrm{pp} \rightarrow \mathrm{p} \mathrm{~N}^{\star}
$$

FIG. 1
where the $N^{\star}$ is produced in the forward direction. Let us consider the consequences on the $z$ component of the $\mathrm{N}^{\star}$ spin. The initial system is described by a plane wave, which can be decorposed into spherical waves (29)

$$
\begin{equation*}
\left|\Omega_{0}, \lambda_{1} \lambda_{2}\right\rangle=\sum_{\mathrm{M}} \sum_{\mathrm{I}} \sqrt{\frac{2 \mathrm{~J}+1}{4 \pi}} \mathcal{D}_{\mathrm{M} \lambda}^{\mathrm{J}^{\star}}\left(\Omega^{\mathrm{o}}\right)\left|\mathrm{JM} \lambda_{1} \lambda_{2}\right\rangle \tag{2}
\end{equation*}
$$

By assuming the z axis lying along the direction of $\hat{\mathrm{p}}_{1}$ (see Fig. 1), it is $\Omega_{0} \equiv(0,0)$, and

$$
\mathcal{D}_{\mathrm{M} \lambda}^{\mathrm{J}^{*}}(0,0)=\delta_{\mathrm{M} \lambda}
$$

so that, in the expression (2), the third component of the total spin turns out to be $\lambda$. This result can be intuitively understood by the following argument.

For each partial wave $J$, consider the component of the spin along the incident proton direcion $\hat{\mathrm{p}}_{1}$

$$
\begin{equation*}
\overrightarrow{\mathrm{J}} \cdot \hat{\mathrm{p}}_{1}=\overrightarrow{\mathrm{s}}_{1} \cdot \hat{\mathrm{p}}_{1}+\overrightarrow{\mathrm{s}}_{2} \cdot \hat{\mathrm{p}}_{2}=\lambda \tag{3}
\end{equation*}
$$

where $\vec{s}_{1}$ and $\vec{s}_{2}$ are the spins of the two initial protons. So the third component along $\hat{p}_{1}$ is independent of J. Now, because the $N^{*}$ direction $\hat{\mathrm{p}}^{\prime}$ in the CMS is very close to $\hat{\mathrm{p}}_{1}$, we can appro ximate with

$$
\begin{equation*}
\overrightarrow{\mathrm{J}} \cdot \hat{\mathrm{p}}_{1} \cong \overline{\mathrm{~J}} \cdot \hat{\mathrm{p}}^{\prime}=\overrightarrow{\mathrm{s}}_{\mathrm{N}^{*}} \cdot \hat{\mathrm{p}}^{\prime}+\overrightarrow{\mathrm{s}}_{3} \cdot \hat{\mathrm{p}}^{\prime}=\Lambda-\lambda_{3} \tag{4}
\end{equation*}
$$

We have indicated the spin of the $\mathbb{N}^{*}$ as $\overrightarrow{\mathrm{s}}_{\mathrm{N}}{ }^{*}$ and $\Lambda$ as its third component in the Jackson referent ce frame (JRF) (29); on the other hand $\overrightarrow{\mathrm{s}}_{3}$ is the spin of the outgoing proton and $\lambda_{3}$ its helicity. From (3) and (4) we can deduce $\lambda \simeq \Lambda-\lambda_{3}$ and, since $|\lambda| \leq 1$, it follows that $|\Lambda| \leqslant 3 / 2$. This argument, which is also applicable in the helicity reference frame (HRF) ${ }^{(29)}$, can be made more rigorous and quantitative by esamining the experimental $\theta_{0}$ distribution for the $N^{\star}$. From (2) we have seen that the third component of the total spin in the forward direction in $\lambda$; we want now to compute the probability to have the same value $\lambda$ in a direction $\Omega_{0} \equiv\left(\theta_{0}, \varphi_{0}\right)$. Since ${ }^{(29)}$

$$
\mathrm{R}\left(\Omega_{0}\right)\left|00 \lambda_{1} \lambda_{2}\right\rangle=\left|\theta_{0}, \varphi_{0}, \lambda_{1}, \lambda_{2}\right\rangle=\sum_{\mathrm{M}} \sum_{\mathrm{J}} \mathrm{~N}^{\mathrm{J}} \mathscr{D}_{\mathrm{M} \lambda}^{\mathrm{J}}\left(\theta_{0}, \varphi_{0}\right)\left|\mathrm{JM} \lambda_{1} \lambda_{2}\right\rangle
$$

the probability density of having $\lambda$ as third component is

$$
\left.\frac{\mathrm{dp}}{\mathrm{~d} \Omega_{0}}=\left|\sum_{J=|\lambda|}^{\infty} \mathrm{N}^{\mathrm{J}} D_{\lambda \lambda}^{J}\left(\theta_{0}, \varphi_{0}\right)\right| \mathrm{J} \lambda \lambda_{1} \lambda_{2}\right\rangle\left.\right|^{2}=\sum_{\mathrm{J}=|\lambda|}^{\infty} \frac{2 \mathrm{~J}+1}{4 \pi}\left[\mathrm{~d}_{\lambda \lambda}^{\mathrm{J}}\left(\theta_{0}\right)\right]^{2} .
$$

By considering the average angle $\bar{\theta}_{\mathrm{O}}$ of the $\mathrm{N}^{\star}$ direction in the CMS, the total probability that $\lambda$ represents the $3^{\text {rd }}$ component of the spin is

$$
\Delta \mathrm{p}=\sum_{\mathrm{J}=\mid \lambda .1}^{\infty}(2 \mathrm{~J}+1) \int_{0}^{\bar{\theta}}\left[\mathrm{d}_{\lambda \lambda}^{\mathrm{J}}\left(\theta_{0}\right)\right]^{2} \mathrm{~d} \cos \theta_{0} .
$$

Therefore the density matrix for the $N^{*}$ produced in proton-proton collision is a $4 \times 4$ matrix; similarly, in pion-pion collision, we will have a $2 \times 2$ matrix. However, we must still take some symmetry properties into account:
a) Owing to parity invariance (both in the HRF and in the JRF) we have

$$
\rho_{\Lambda \Lambda^{\prime}}^{\mathrm{J}}=(-)^{\Lambda-\Lambda^{\prime}} \rho_{-\Lambda-\Lambda^{\prime}}^{\mathrm{J}}
$$

which is true in every frame with the $y$ axis normal to the decay plane.
b) The density matrix is a hermitian operator:
c) Last

$$
\rho_{\Lambda \Lambda^{\prime}}^{\mathrm{J}}=\left(\rho_{\Lambda^{\prime} \Lambda}^{\mathrm{J}}\right)^{*} .
$$

$$
\operatorname{tr} \rho=\sum_{\Lambda} \rho_{\Lambda \Lambda}=1
$$

Then the density matrix for $p p$ collisons has 7 independent parameters

$$
\left(\begin{array}{llll}
a & b+i c & d+i e & \text { if }  \tag{5}\\
b-i c & \frac{1}{2}-a & i g & d-i e \\
d-i e & -i g & \frac{1}{2}-a & -b+i c \\
-i f & d+i e & -b-i c & a
\end{array}\right)
$$

The $a, b, c, d, e, f$ are real parameters, with $0 \leq a \leq \frac{1}{2}$.
Now we examine what are the consequences of assuming spin 0 or 1 particle exchange in the crossed t-channel:

$$
\overline{\mathrm{p}} \mathrm{p} \rightarrow \mathrm{~s} \rightarrow \overline{\mathrm{p}} \mathrm{~N}^{*}
$$

where $s$ is an intermediate virtual particle.
We are in the JRF, where the quantization axis is along the direction of the momentum trans fer $\vec{\Delta}$ in the $N^{*}$ center of mass:
a) By assuming that only a spin 0 virtual particle is exchanged, we expect that the $z$ component of the $N{ }^{s}{ }_{\wedge}^{115}{ }^{2}+1 / 2$, so the total production amplitude contains only two terms. We can factorize the reaction and keep only

$$
\begin{equation*}
0 \rightarrow \overline{\mathrm{p}} \mathrm{~N}^{\star} \tag{6}
\end{equation*}
$$

for which we have $\mathrm{A}_{\frac{1}{2}-\frac{1}{2}}=\mathrm{A}-\frac{1}{2} \frac{1}{2}$
(due to parity conservation). In this hypothesis the density matrix is
4.

$$
\rho=\left(\begin{array}{ll}
\frac{1}{2} & \rho_{1-1} \\
-\rho_{1-1} & \frac{1}{2}
\end{array}\right)
$$

b) If also a spin 1 virtual particle is exchanged, other matrix elements must be taken into account, but with some limitations. The amplitudes to be considered are, in this case

$$
\begin{equation*}
{ }^{\text {B }}-\frac{1}{2} \frac{3}{2} \quad \mathrm{~B}_{\frac{1}{2} \frac{1}{2}} \quad \mathrm{~B}_{\frac{1}{2}}-\frac{1}{2} \quad{ }^{\mathrm{B}}-\frac{1}{2} \frac{1}{2} \quad{ }^{\mathrm{B}}-\frac{1}{2}-\frac{1}{2} \quad{ }^{\mathrm{B}_{1}}-\frac{3}{2} \tag{7}
\end{equation*}
$$

Then from (6) and (7) we have

$$
\rho_{3-3}=\sum_{\Lambda} F_{\lambda \frac{3}{2}} F_{\lambda-\frac{3}{2}}^{*}=F_{\frac{1}{2} \frac{3}{2}} F_{\frac{1}{2}-\frac{3}{2}}^{*}+\mathrm{F}_{-\frac{1}{2} \frac{3}{2}} \mathrm{~F}^{\star}-\frac{1}{2}-\frac{3}{2} .
$$

So if the experimental value of $\rho_{3-3}$ is not consistent with 0 , we can deduce that there is an exchange of spin $>1$. Similarly, if we assume that the main contribution comes from spin 0 exchange (i.e. $B \ll A$ ), we have, at first order for the $B$ amplitudes, only three independent nonvanishing matrix elements : $\rho_{11}, \rho_{1-1}$ and $\rho_{31}$, as one can see by writing these matrix elements and inserting the amplitudes ( 6 ) and (7) into their expressions.

## 2. - DECAY ANGULAR DISTRIBUTION. -

The angular distribution for the normal to the $\mathrm{N}^{*}$ decay plane is ${ }^{(29)}$

$$
\begin{equation*}
I(\theta, \varphi)=\frac{2 J+1}{4 \pi} \sum_{\Lambda \Lambda^{\prime}}^{\Sigma} \rho_{\Lambda \Lambda^{\prime}}^{J} \sum_{\mu}^{J} \varnothing_{\Lambda \mu}^{J^{\star}}(\theta, \varphi) \not D_{\Lambda^{\prime} \mu}^{J}(\theta, \varphi) g_{\mu}^{J} \tag{8}
\end{equation*}
$$

where $(\theta, \varphi)$ is the direction of the normal with respect to the JRF or to the HRF, and $\Lambda, \Lambda^{\prime}$ values of the third component of the $\mathrm{N}^{\star}$ spin (either in HRF or in JRF).

The $\mathrm{g}_{\mu}^{\mathrm{J}}$ are defined in Chung ${ }^{(29)}$ : it must be

$$
\begin{equation*}
\sum_{\mu=J}^{J} g_{\mu}^{J}=1 \tag{9}
\end{equation*}
$$

By fitting the experimental distribution with the above function, one could determine, in principle:
a) the spin of the $N^{*}$, by fitting the distribution with different values of J ;
b) the matrix elements of the resonance ( 7 independent real parameters for the $N^{\star}$, as stated before).

However, in most cases it looks quite difficult to fit the experimental data with $2 \mathrm{~J}+7$ parameters. In the following, we will present some alternative methods to determine both the spin and the production and the decay parameters.
2.1. - Fitting method. -

By integrating (8) over the azimuthal angle, one obtains:

$$
\begin{align*}
& I(\theta)=\frac{2 J+1}{2} \quad \sum_{\mu} \sum_{\Lambda}^{\Sigma} \rho_{\Lambda \Lambda}^{J}\left[d_{\Lambda \mu}^{J}(\theta)\right]^{2} g_{\mu}^{J}=  \tag{10}\\
& \quad=\frac{2 J+1}{2} \\
& \quad \sum_{\mu}\left\{a\left[d_{3 \mu}^{J}(\theta)\right]^{2}+\left(\frac{1}{2}-a\right)\left[d_{1 \mu}^{J}(\theta)\right]^{2}\right\}\left(g_{\mu}^{J}+g_{-\mu}^{J} 0\right)
\end{align*}
$$

where $a$ is the parameter defined in (5).
So we have a function with $2 \mathrm{~J}+1$ free parameters, taking into account the condition (9). Then, we can determine the nondiagonal matrix elements by fitting the distribution in $\theta, \varphi$ with the expression (8), or by fitting the integrated expression $I(\varphi)$ :

$$
\begin{equation*}
I(\varphi)=\frac{2 \mathrm{~J}+1}{4 \pi} \sum_{\Lambda \Lambda^{\prime}} \rho_{\Lambda \Lambda^{\prime}}^{\mathrm{J}} \sum_{\mu} \mathrm{e}^{\mathrm{i}\left(\Lambda-\Lambda^{\prime}\right) \varphi} \mathrm{g}_{\mu}^{\mathrm{J}} \int \mathrm{~d} \cos \theta \mathrm{~d}_{\Lambda \mu}^{\mathrm{J}}(\theta) \mathrm{d}_{\Lambda^{\prime} \mu}^{\mathrm{J}}(\theta) \tag{11}
\end{equation*}
$$

We have to deal with 6 real parameters, since the remaining have been already determined.
Also the hypothesis that the helicity is conserved in diffractive production can be tested experimentally by analizing the distribution $I(\varphi)$ in the HRF (in this case we test SCHC) or in the JRF (then we test TCHC). Helicity conservation implies $(30)$ that $\Lambda=\Lambda^{\prime}=\lambda_{1}$. From (11) it follows that the angular distribution is independent of the azimuthal angle. It can be useful to evaluate the moments of (11):

$$
\mathrm{I}(\varphi)=\sum_{\nu} \mathrm{G}_{\nu} \mathrm{e}^{\mathrm{i} \nu \varphi} \quad \mathrm{G}_{\nu}=\frac{1}{2 \pi \mathrm{~N}} \sum_{\mathrm{k}=1}^{\mathrm{N}} \mathrm{e}^{-\mathrm{i} \nu \varphi_{\mathrm{k}}}
$$

where $N$ is the total number of events. The defined moments allow us to evaluate helicity conser vation violations. We note that this holds even if there is more than one (partial) decaying wave.

## 2.2. - Moments method. -

The distribution (10) can be written as ${ }^{(29)}$

$$
I(\theta)=\sum_{L=0}^{2 J} \sqrt{\pi(L+1)} \sum_{\mu=-J}^{J} C_{\mu \circ \mu}^{J L J}\left(g_{\mu}^{J}+g_{-\mu}^{J}\right)\left[a C_{303}^{J L J}+\left(\frac{1}{2}-a\right) C_{1}^{J} \operatorname{L} J_{1}\right] Y_{0}^{L}(\theta)
$$

We define the moments

$$
\begin{equation*}
M_{L}=\frac{1}{N} \sum_{i=1}^{N} Y_{0}^{L}\left(\theta_{i}\right)=\sqrt{\pi(L+1)} \sum_{\mu} C_{\mu \circ \mu}^{J L J}\left(g_{\mu}^{J}+g_{-\mu}^{J}\right)\left[a C_{303}^{J L J}+\left(\frac{1}{2}-a\right) C_{101}^{J L J}\right] \tag{12}
\end{equation*}
$$

Since the number of moments equals the number of unknown parameters, we can solve the linear system (12).

Once the $g_{\mu}^{J}$ and "a" have been determined, we can apply the moments method also to the distribution (8), for which the moments are defined as ${ }^{(29)}$ :

$$
H(L, m)=\frac{1}{N} \sum_{k=1}^{N} \varnothing_{m o}^{L}\left(\theta_{k}, \varphi_{k}\right)
$$

with
2.3. - The decay angular distribution can be parametrized in more convenient ways if we developed $\mathrm{g}_{\mu}^{\mathrm{J}}(29,31)$ :

$$
\begin{equation*}
g_{\mu}^{J}=\frac{1}{2^{4}(2 \pi)^{8}} \sqrt{\frac{s-M^{2}}{2 s}} \int d W d E_{1} d E_{2} \frac{W \sum_{\mu}\left|F_{\mu}^{J}\right|^{2}}{\left(W-W_{o}\right)^{2}+\Gamma_{\text {tot }} W_{o}^{2}} \tag{13}
\end{equation*}
$$

where $F_{\mu}^{J}(\lambda)$ is the invariant decay amplitude of the $\mathrm{N}^{*} \rightarrow \mathrm{p}^{+} \pi^{-}, \quad \lambda \quad$ being the helicity of the proton and $\mu$ the $Z$ component of the $N^{\dot{*}}$ spin along the body - fixed frame ${ }^{(29)}$. Hence, deve'on ing in partial waves
6.

$$
\begin{aligned}
& F_{\mu}^{J}(\lambda)=\sum_{\mathrm{m}} \mathrm{~d}_{\lambda \mathrm{m}}^{\frac{1}{2}}\left(\frac{\pi}{2}\right) \mathrm{F}_{\mu}^{J}(\mathrm{~m})=\sqrt{\frac{4 \pi(2 \mathrm{~L}+1)}{2 \mathrm{~J}+1}} \sum_{\mathrm{m}} \mathrm{~d}_{\lambda \mathrm{m}}^{\frac{1}{Z}}\left(\frac{\pi}{2}\right) C_{M \mathrm{Mm}}^{\mathrm{L}} \frac{1}{2} J \sum_{\mathrm{k}=0}^{\mathrm{L}} \mathrm{~S}_{\mathrm{k}} \cdot
\end{aligned}
$$

We have expressed the helicity state as a function of the states with the third component m with respect to the $Z$ axis in the body - fixed frame. L is the total orbital angular momentum, and due to parity conservation it must be either $\mathrm{J}-1 / 2$ or $\mathrm{J}+1 / 2$, but not a mixture of the two waves.

If $\mathrm{N}^{\star}$ is diffractively produced, Morrison's rule ${ }^{(32)}$ suggeststhat $L=J-1 / 2$ : this hypothesis can be tested.

In this connection we observe that the factorization ${ }^{(32)}$ could be usefully tested for the reactions (1), in order to further investigate the production mechanism.

If we set:

$$
\begin{array}{ll}
a=\int d W d E_{1} d E_{2} K(W)\left|A_{\mu-\frac{1}{2}}^{L}\right|^{2} & a>0 \\
b=\int d W d E_{1} d E_{2} K(W)\left|A_{\mu+\frac{1}{2}}^{L}\right|^{2} & b>0 \\
c+i d=\int d W d E_{1} d E_{2} K(W) A^{L} A_{\mu-\frac{1}{2}} A^{L *}+\frac{1}{2} &
\end{array}
$$

(see Chung ${ }^{(29)}$ fon expression of $K(W)$ ),
we can express the $g_{\mu}^{J}$ in the distributions(8), (10), (11) as functions of $a, b, c, d$. Because of condition (9), we have 3 free parameters in all.

This method is the most convenient, since we can test the two different orbital angular momentum apmlitudes with only 3 parameters; however we loose information about the decay parameters. Therefore we consider an alternative method, useful also in the Dalitz plot distribution analysis (see sect. 4). We know that the $\mathrm{N}^{\dot{4}}$ decays into:
a)

$$
\mathrm{p} \pi^{+} \pi^{-} \quad \text { incoherently }: \mathrm{I}_{\mu}^{J}
$$

b)

$$
\mathrm{p} \rho^{\circ}
$$

$$
\begin{equation*}
: R_{\mu}^{J} \tag{14}
\end{equation*}
$$

c)
$\Delta^{++} \pi^{-}$
$: \Delta_{\mu}^{J}$
d)
$\mathrm{N}^{\mathrm{O}} \pi^{+}$
$: N_{\mu}^{J}$.

So we can write :

$$
F_{\mu}^{J}=I_{\mu}^{J}+R_{\mu}^{J}+\Delta_{\mu}^{J}+N_{\mu}^{J}
$$

and developing in partial waves, we obtain:

$$
\left.F_{\mu}^{J}=\sqrt{\frac{4 \pi(L+1)}{2 J+1}} \sum_{m} d_{\lambda m}^{\frac{1}{2}}\left(\frac{\pi}{2}\right) C_{M m \mu}^{L_{M}} \sum_{K=0}^{L}{ }_{K}^{L} M_{M}^{K} S_{k}+a_{M}^{1}\left(b_{1}+c_{1}+d_{1}\right)\right]
$$

$$
\begin{align*}
& a_{\mathrm{M}}^{\mathrm{K}}=\sum_{\mathrm{m}_{1} \mathrm{~m}_{2}} C_{\mathrm{m}_{1} \mathrm{~m}_{2} \mathrm{M}}^{\mathrm{KL}-\mathrm{K} \mathrm{~L}} \\
& \sum_{\lambda}\left|F_{\mu}^{J}(\lambda)\right|^{2}=\sum_{\lambda m_{m^{\prime}}} G_{\lambda m m^{\prime}}^{\mu}\left[\sum_{\mathrm{k}} a_{M_{M}}^{\mathrm{K}}{ }^{\mathrm{K}}{ }_{\mathrm{M}^{\prime}}^{\mathrm{K}}\left|\mathrm{~S}_{\mathrm{k}}\right|^{2}+a_{\mathrm{M}^{1}}^{1} \alpha_{\mathrm{M}^{\prime}}^{1}\left|\mathrm{~b}_{1}+\mathrm{c}_{1}+\mathrm{d}_{1}\right|^{2}\right] \tag{15}
\end{align*}
$$

where $S_{k}$ are the partial amplitudes of the $N^{\star}$ incoherent decay. Of course they don't interfere neither among them, nor with the partial decay modes. On the other hand, we have:

$$
\mathrm{R}_{\mu}^{\mathrm{J}}=\operatorname{cost} \sum_{\mathrm{m}=-\frac{1}{2}}^{\frac{1}{2}} \mathrm{~d}_{\lambda \mathrm{m}}^{\frac{1}{2}}\left(\frac{\pi}{2}\right) \mathrm{C}_{\mathrm{Mm} \mu}^{\mathrm{L} \frac{1}{2} \mathrm{~J}} a_{M}^{1} b_{1}
$$

and similar expressions for $\Delta_{\mu}^{3}$ and $N_{\mu}^{J}$.
The sum over partial waves runs from 0 to $L$, because only the lowest possible angular momenta are supposed to contribute to the amplitude. More precisely, for a given total orbital angular momentum $L$, if $1_{1}$ is the angular momentum of the system and $1_{2}$ the orbital angular momentum of the proton with respect to the same system, we take into account only the values for which $L=I_{1}+1_{2}$.

The order of magnitude for the neglected amplitudes has been evaluated with non relativistic scattering formulas ${ }^{(33)}$ : the greatest of these amplitudes results to be $\approx 10 \%$ of the amplitudes taken into account.

In conclusion it results :

$$
\mathrm{g}_{\mu}^{J}=\sum_{\lambda \mathrm{m}^{\prime}} \mathrm{G}_{\lambda \mathrm{m} \mathrm{~m}^{\prime}}^{\mu}\left(a_{\mathrm{M}}^{1} a_{\mathrm{M}^{\prime}}^{1} \mathrm{R}+\sum_{\mathrm{k}} a_{\mathrm{M}}^{\mathrm{K}} a_{\mathrm{M}^{\prime}}^{\mathrm{K}} A_{\mathrm{K}}\right)
$$

where

$$
\begin{aligned}
& \mathrm{R}=\int \mathrm{dW} \mathrm{dE} 1 \mathrm{dE}_{2} \mathrm{~K}(\mathrm{~W})\left|\mathrm{b}_{1}+\mathrm{c}_{1}+\mathrm{d}_{1}\right|^{2} \\
& A_{K}=\int \mathrm{dW} \mathrm{dE} E_{1} d E_{2} K(W)\left|S_{k}\right|^{2}
\end{aligned}
$$

So $g_{\mu}^{J}$ can be expressed as functions of $R$ and $A_{K}$; they are $L+2$ positive parameters which can be related to same parameters of the Dalitz plot distribution (See the following section).

## 3. - DALITZ PLOT ANALYSIS, -

If $W$ is the effective mass of the $p \pi^{+} \pi^{-}$system and $E_{1}, E_{2}$ the pions energies in the CMS, the Dalitz plot fitting function is $(29,31)$ :

$$
\begin{equation*}
I\left(W, E_{1}, E_{2}\right)=\frac{1}{2^{4}(2 \pi)^{8}} \sqrt{\frac{s-\mathrm{M}^{2}}{\mathrm{~s}}} \mathrm{~W}\left[\frac{\varepsilon \sum_{\mu}\left|\mathrm{F}_{\mu}^{J}\right|^{2}}{\left(\mathrm{~W}^{2}-\mathrm{W}_{\mathrm{o}}^{2}\right)+J_{\text {tot }}^{2} \mathrm{~W}_{\mathrm{o}}^{2}}+(1-\varepsilon) \mathrm{f}\left(\mathrm{~W}, \mathrm{E}_{1}, \mathrm{E}_{2}\right) \alpha\left(\mathrm{W}-\mathrm{W}_{\min }\right)\left(\mathrm{W}_{\max }-\mathrm{W}\right)\right] \tag{16}
\end{equation*}
$$

where $s$ is the Mandelstam variable of the whole system, $M$ is the mass of the nucleon, $\varepsilon$ the per centage of the resonant amplitude $(0<\varepsilon<1), F_{\mu}^{J}$ the decay amplitudes of the $N^{\star}$ and $f\left(E_{1}, E_{2}, \bar{W}\right)$ a function to be defined below. In the formula ( $1 \frac{\mu}{6}$ ), we assume that the Breit-Wigner resonance and the background add incoherently. The background is supposed to be a smooth function vanishing at the minimum $\left(W_{\min }\right)$ and at the maximum $\left(W_{\max }\right)$ value of $W$, with a similar hypothesis for $f\left(E_{1}, E_{2}, W\right)$, as we shall see; $\alpha$ is a positive parameter.

We impose ${ }^{(31)}$ the condition:
8.

$$
\frac{1}{(4 \pi)^{3}(2 J+1)} \int \mathrm{dE}_{1} \mathrm{dE}_{2} \sum_{\mu}\left|\mathrm{F}_{\mu}^{J}\right|^{2}=\mathrm{W}_{\mathrm{o}} \Gamma\left(\mathrm{~W}_{\mathrm{o}}\right)
$$

We note that in this case $\Gamma\left(W_{0}\right)$ is the partial width for the $N^{*}$ decay into $\mathrm{p} \pi^{+} \pi^{-}$, while in (15) tot is the total $\mathrm{N}^{\star}$ with ${ }^{(31)}$.

In order to have the normalization $\int I\left(W E_{1} E_{2}\right) d W d E_{1} d E_{2}=1$, we must set:

$$
\begin{equation*}
a \int f\left(E_{1} E_{2} W\right)\left(\frac{1}{2^{4}(2 \pi)^{8}} \sqrt{\frac{s-M^{2}}{s}} W d W d E_{1} d E_{2}=1\right. \tag{17}
\end{equation*}
$$

The percentage $\varepsilon$ can be determined by integrating (15) over $\mathrm{dE}_{1}$ and $\mathrm{dE}_{2}$ and fitting the effecti ve mass distribution:

$$
I(W)=\frac{1}{2^{4}} \frac{1}{(2 \pi)^{8}} \sqrt{\frac{\mathrm{~s}-\mathrm{M}^{2}}{\mathrm{~s}}} \mathrm{~W}\left[\varepsilon \frac{(4 \pi)^{3}(2 \mathrm{~J}+1) \mathrm{W}_{\mathrm{o}} \Gamma(\mathrm{~W})}{\left(\mathrm{W}^{2}-\mathrm{W}_{\mathrm{o}}^{2}\right)^{2}+\mathrm{W}_{\mathrm{o}}^{2} \Gamma_{\text {tot }}^{2}}+(1-\varepsilon) \mathrm{F}(\mathrm{~W}) \alpha\left(\mathrm{W}-\mathrm{W}_{\min }\right)\left(\mathrm{W}_{\max }-\mathrm{W}\right)\right]
$$

where $F(W)=\int d E_{1} d E_{2} f\left(E_{1} E_{2} W\right)$.
As we shall see (cfr. (21)), $F(W)$ does not depend on $W$. We now check the function $\sum_{\mu}\left|F_{\mu}^{J}\right|^{2}$ in detail. Taking into account the previous hypothesis about the decay modes (see end of section 3), we may write $\sum_{\mu}\left|F_{\mu}^{J}\right|^{2}$ following Zemach ${ }^{(34)}$ notation. The sum over the spin components results to be the contaction of an irreducible J-th rank tensor with its coniugate, the irreducible tensor being constructed by the $\pi^{+}, \pi^{-}$momenta. It results :

$$
\begin{equation*}
\sum_{\mu}\left|F_{\mu}^{J}\right|^{2}=\sum_{k=0}^{L} a_{k} T_{k}^{J}: T_{k}^{J J^{\star}}+\tau^{J}: \tau^{J^{\star}} \tag{18}
\end{equation*}
$$

where

$$
\begin{aligned}
& \mathrm{T}_{\mathrm{o}}^{\mathrm{J}}=\mathrm{T}^{\mathrm{J}}\left(\overrightarrow{\mathrm{p}}_{1}\right) \quad \mathrm{T}_{1}^{J}=\mathrm{T}^{\mathrm{J}}\left(\overrightarrow{\mathrm{p}}_{1} \ldots \overrightarrow{\mathrm{p}}_{1} \overrightarrow{\mathrm{p}}_{2}\right) \\
& \mathrm{T}_{\mathrm{k}}^{\mathrm{J}}=\mathrm{T}^{\mathrm{J}}\left(\overrightarrow{\mathrm{p}}_{1} \ldots \overrightarrow{\mathrm{p}}_{1}, \overrightarrow{\mathrm{p}}_{2} \ldots \overrightarrow{\mathrm{p}}_{2}\right) \quad\left(\overrightarrow{\mathrm{p}}_{2} \text { appears k times }\right) .
\end{aligned}
$$

In ref. (18) we have indicated with $p_{1}$ and $p_{2}$ the $\pi^{+}$and $\pi^{-}$momenta in the $N^{*}$ rest frame. As in ref. (14) formula (18) contains $L+1$ partial waves which add incoherently and which are described by the $T_{\mathrm{K}}^{\mathrm{J}}$; furthermore, it contains the partial decay modes we have previously seen in (13), described by $\tau^{J}$ :

$$
\begin{gathered}
\tau^{J}=b_{\Delta} B_{\Delta}\left(W_{13}\right) T^{J}\left(\vec{p}_{2} \ldots \overrightarrow{\mathrm{p}}_{2}, \overrightarrow{\mathrm{p}}_{1}-\overrightarrow{\mathrm{p}}_{3}\right)+e^{i \varphi} b_{N} B_{N}\left(\mathrm{w}_{23}\right) T^{J}\left(\overrightarrow{\mathrm{p}}_{1} \ldots \overrightarrow{\mathrm{p}}_{1}, \overrightarrow{\mathrm{p}}_{2}-\overrightarrow{\mathrm{p}}_{3}\right)+ \\
+e^{i \psi} b_{\rho} B_{\rho}\left(\mathrm{w}_{12}\right) \mathrm{T}^{J}\left(\overrightarrow{\mathrm{p}}_{3} \ldots \overrightarrow{\mathrm{p}}_{3}, \overrightarrow{\mathrm{p}}_{1}-\overrightarrow{\mathrm{p}}_{2}\right)
\end{gathered}
$$

where $p_{3}$ is the proton momentum in the $N^{\star}$ rest frame, $W_{12}$ the effective mass of the $\pi^{+} \pi^{-}$ system, ${ }^{3} W_{13}$ the mass of $p \pi^{-}$and $W_{23}$ the mass of $p \pi^{-} . \mathscr{B}_{\Delta}\left(W_{13}\right)$ is the $\Delta^{++}$propagator:

$$
\mathcal{B}_{\Delta}\left(\mathrm{w}_{13}\right)=\left[\mathrm{w}_{13}^{2}-\mathrm{M}_{\Delta}^{2}-\mathrm{i} \Gamma_{\Delta} \mathrm{m}_{\Delta}\right]^{-1}
$$

with analogous formulas for $B_{\rho}\left(W_{12}\right)$ and $B_{N}\left(W_{23}\right)$. The $b, b_{\Delta}, b_{N}$ are real positive parameters, $\varphi$ and $\psi$ are the relative phases of the $\rho$ and the $N^{*} \circ(147 \hat{0})$ decay amplitudes with respect
to the $\Delta^{++}$amplitude.
In Appendix I we illustrate a differential technique to calculate the contraction of the irreducible tensors, and we present a general formula for $T^{J}: T$. ${ }^{J Y}$. Here we summarize the results for the most likely spin assignements for the $\mathbb{N}^{\star}: J=5 / 2$ and $7 / 2$.

$$
\begin{aligned}
J=\frac{5}{2} \quad \sum_{\mu}\left|F_{\mu}^{\frac{5}{2}}\right|^{2}= & a_{o} T^{\frac{5}{2}}\left(\overrightarrow{\mathrm{p}}_{1}\right): T^{\frac{5}{2}}\left(\overrightarrow{\mathrm{p}}_{1}\right)+\mathrm{a}_{1} T^{\frac{5}{2}}\left(\overrightarrow{\mathrm{p}}_{1}, \overrightarrow{\mathrm{p}}_{2}\right): T^{\frac{5^{*}}{2}}\left(\overrightarrow{\mathrm{p}}_{1} \overrightarrow{\mathrm{p}}_{2}\right)+ \\
& +\mathrm{a}_{2} T^{\frac{5}{2}}\left(\overrightarrow{\mathrm{p}}_{2}\right): T^{\frac{5^{*}}{2}}\left(\overrightarrow{\mathrm{p}}_{2}\right)+\zeta^{\frac{5}{2}}: \zeta^{\frac{5^{*}}{2}}
\end{aligned}
$$

where

$$
\mathrm{J}=\frac{7}{2} \quad \sum_{\mu}\left|\mathrm{F}_{\mu}^{\frac{7}{2}}\right|^{2}=\mathrm{c}_{\mathrm{o}} \mathrm{~T}^{\frac{7}{2}}\left(\overrightarrow{\mathrm{p}}_{1}\right): \mathrm{T}^{\frac{7^{*}}{2}}\left(\overrightarrow{\mathrm{p}}_{1}\right)+\mathrm{c}_{1} \mathrm{~T}^{\frac{7}{2}}\left(\overrightarrow{\mathrm{p}}_{1} \overrightarrow{\mathrm{p}}_{1} \overrightarrow{\mathrm{p}}_{2}\right): \mathrm{T}^{\frac{7^{*}}{2}}\left(\overrightarrow{\mathrm{p}}_{1} \overrightarrow{\mathrm{p}}_{1} \overrightarrow{\mathrm{p}}_{2}\right)+
$$

$$
+\mathrm{c}_{2} \mathrm{~T}^{\frac{7}{2}}\left(\overrightarrow{\mathrm{p}}_{1} \overrightarrow{\mathrm{p}}_{2} \overrightarrow{\mathrm{p}}_{2}\right): \mathrm{T}^{\frac{7^{*}}{2}}\left(\overrightarrow{\mathrm{p}}_{1} \overrightarrow{\mathrm{p}}_{2} \overrightarrow{\mathrm{p}}_{2}\right)+\mathrm{c}_{3} \mathrm{~T}^{\frac{7}{2}}\left(\overrightarrow{\mathrm{p}}_{2}\right): \mathrm{T}^{\frac{7^{*}}{2}}\left(\overrightarrow{\mathrm{p}}_{2}\right)+\zeta^{\frac{7}{2}}: \zeta^{\frac{7^{*}}{2}}
$$

where last term is similar to $\zeta^{\frac{5}{2}}: \tau^{\frac{5}{2}}$.
To have explicitly the tensor contractions, the following expressions are useful ( J half-integer, $\mathrm{L}=\mathrm{J}-{ }^{1} / 2$ ). (See Appendix).

$$
\begin{aligned}
& T^{J}(\vec{p}): T^{J^{*}(\vec{p})}=\frac{C_{L} p^{2 L}}{2 L+1}\left(L^{2}+1\right) \\
& T^{J}(\vec{p} \ldots \vec{p} \vec{a}): T^{J^{*}}(\vec{p} \ldots \vec{p} \vec{a})=\frac{C_{L} p^{2 L}(L+1)}{2 L+1}\left\{\left(\frac{\hat{p} \cdot \vec{a}}{p}\right)^{2}+\frac{P_{L}^{\prime}(1)}{p^{2}}\left[a^{2}-(\hat{p} \cdot \vec{a})^{2}\right]\right\} \\
& T^{J}(\vec{p} \ldots \vec{p} \vec{b}): T^{J}(\vec{q} \ldots \vec{q} \vec{a})=\frac{C_{L^{p}} p^{L}{ }^{L}(L+1)}{2 L+1}\left\{\frac { \hat { q } \cdot \vec { a } } { q } \left[\frac{\hat{p} \cdot \vec{b}}{p} P_{L}(x)+\frac{P_{L}^{\prime}(x)}{L} d y+\right.\right. \\
& \left.\left.\quad+\frac{1}{L} \frac{\hat{p} \cdot \vec{b}}{p} P_{L}^{\prime}(x) d x+\frac{1}{L^{2}} P_{L}^{\prime \prime}(x) d x d y+P_{L}^{\prime}(x) \delta(d x)\right]\right\}
\end{aligned}
$$

where $P_{L}(x)$ is the L-th Legendre Polynomial, $P_{L}^{\prime}(x)$ and $P_{\mathrm{L}}^{\prime \prime}(x)$ are its first and second derivatives; $\mathrm{x}=\hat{\mathrm{p}} . \hat{\mathrm{q}}$, where $\hat{\mathrm{p}}$ and $\hat{\mathrm{q}}$ are the unit vectors of $\overrightarrow{\mathrm{p}}$ and $\overrightarrow{\mathrm{q}}$. The $\mathrm{dx}, \mathrm{dy}, \delta(\mathrm{dx})$ are defined in the Appendix.

$$
\begin{aligned}
& \zeta^{\frac{5}{2}}: \zeta^{\frac{5^{*}}{2}}={ }_{\Delta}^{2}\left|\beta_{\Delta}\left(W_{13}\right)\right|^{2} T^{\frac{5}{2}}\left(\vec{p}_{2}, \overrightarrow{\mathrm{p}}_{1}-\overrightarrow{\mathrm{p}}_{3}\right): \mathrm{T}^{\frac{5^{*}}{2}}\left(\overrightarrow{\mathrm{p}}_{2}, \overrightarrow{\mathrm{p}}_{1}-\overrightarrow{\mathrm{p}}_{3}\right)+\mathrm{b}_{\mathrm{N}}^{2}\left|\beta_{\mathrm{N}}\left(\mathrm{~W}_{13}\right)\right|^{2} . \\
& \text { - } T^{\frac{5}{2}}\left(\overrightarrow{\mathrm{p}}_{1}, \overrightarrow{\mathrm{p}}_{2}-\overrightarrow{\mathrm{p}}_{3}\right): \left.\mathrm{T}^{\frac{5^{*}}{2}}\left(\overrightarrow{\mathrm{p}}_{1}, \overrightarrow{\mathrm{p}}_{2}-\overrightarrow{\mathrm{p}}_{3}\right)+\mathrm{b}_{\rho}^{2} \right\rvert\, \beta\left(\mathrm{W}_{12}\right)^{2} \mathrm{~T}^{\frac{5}{2}}\left(\overrightarrow{\mathrm{p}}_{3}, \overrightarrow{\mathrm{p}}_{1}-\overrightarrow{\mathrm{p}}_{2}\right): \mathrm{T}^{\frac{5^{*}}{}}\left(\overrightarrow{\mathrm{p}}_{3}, \overrightarrow{\mathrm{p}}_{1}-\overrightarrow{\mathrm{p}}_{2}\right)+ \\
& +2 \mathrm{~b}_{\Delta}{ }_{N} \operatorname{Re}\left[\mathrm{e}^{-\mathrm{i} \varphi} \mathcal{B}_{\Delta}\left(\mathrm{W}_{13}\right) \mathcal{B}_{N}^{*}\left(\mathrm{~W}_{23}\right) \mathrm{T}^{\frac{5}{2}}\left(\overrightarrow{\mathrm{p}}_{2}, \overrightarrow{\mathrm{p}}_{1}-\overrightarrow{\mathrm{p}}_{3}\right): \mathrm{T}^{\frac{5^{*}}{2}}\left(\overrightarrow{\mathrm{p}}_{1}, \overrightarrow{\mathrm{p}}_{2}-\overrightarrow{\mathrm{p}}_{3}\right)+\right. \\
& +2 \mathrm{~b}_{\mathrm{N}} \mathrm{~b}_{\rho} \operatorname{Re}\left[\mathrm{e}^{-\mathrm{i}(\varphi+\psi)} \mathcal{B}_{\mathrm{N}}\left(\mathrm{~W}_{23}\right) \beta_{\rho}^{*}\left(\mathrm{~W}_{12}\right)\right]^{\frac{5}{2}}\left(\overrightarrow{\mathrm{p}}_{1}, \overrightarrow{\mathrm{p}}_{2}-\overrightarrow{\mathrm{p}}_{3}\right): \mathrm{T}^{\frac{5^{ \pm}}{2}}\left(\overrightarrow{\mathrm{r}}_{3}, \overrightarrow{\mathrm{p}}_{1}-\overrightarrow{\mathrm{p}}_{2}\right)
\end{aligned}
$$

10. 

The parameters $a_{0}, a_{1}, a_{2}, c_{0}, c_{1}, c_{2}, c_{3}$ are real and positive and can be considered as free parameters; however they can be related to the decay parameters appearing in expression (14). By comparing this expression with (18), we obtain;

$$
\begin{align*}
& a_{k} \mathrm{~T}_{\mathrm{k}}^{\mathrm{J}}: \mathrm{T}_{\mathrm{k}}^{\mathrm{J}^{*}}=\sum_{\mu} \sum_{\lambda \mathrm{MM}^{\prime}} G^{G^{\mu}}{M M^{\prime}}^{a_{M}^{k}} a_{M^{\prime}}^{\mathrm{k}}\left|\mathrm{~S}_{\mathrm{k}}\right|^{2}  \tag{19}\\
& \tau^{\mathrm{J}}: \tau^{\mathrm{J}^{*}}=\sum_{\mu} \sum_{\lambda \mathrm{MM}^{\prime}} \mathrm{G}^{\mu} \lambda \mathrm{MM}^{\prime} a_{M}^{1}{ }^{a^{\prime}}{ }_{\mathrm{M}^{\prime}}\left|\mathrm{b}_{1}+\mathrm{c}_{1}+\mathrm{d}_{1}\right|^{2} \tag{20}
\end{align*}
$$

Therefore

$$
\begin{aligned}
& \int \mathrm{dW} \mathrm{dE} E_{1} \mathrm{dE}_{2} \mathrm{~K}(\mathrm{~W}) \mathrm{a}_{\mathrm{k}} \mathrm{~T}_{\mathrm{k}}^{\mathrm{J}}: \mathrm{T}_{\mathrm{k}}^{\mathrm{J}^{*}}=\sum_{\mu} \sum_{\lambda \mathrm{MM}^{\prime}} G_{\lambda \mathrm{MM}^{\prime}}^{\mu} a_{M^{k}}^{\mathrm{k}} a_{M^{\prime}}^{\mathrm{k}} A_{\mathrm{k}} \\
& \int \mathrm{dW} \mathrm{dE} E_{1} \mathrm{dE}_{2} \mathrm{~K}(\mathrm{~W}) \zeta^{\mathrm{J}}: \zeta^{\mathrm{J}^{*}}=\sum_{\mu} \sum_{\lambda \mathrm{MM}^{\prime}} G^{\mu}{ }_{\lambda \mathrm{MM}^{\prime}} a_{M_{M}}^{1} a_{M^{\prime}}^{1} \mathrm{R} .
\end{aligned}
$$

So we determine the parameters $\mathrm{a}_{\mathrm{k}}$ and a relation among $\mathrm{b}_{\Delta}, \mathrm{b}_{\mathrm{N}}, \mathrm{b}_{\rho}, \varphi, \psi$.
Last, we try to describe the background with a phenomenological function. The system $p \pi^{+} \pi^{-}$ can contain the following states:
a) $\mathrm{N}^{\star}$ resonance
b) $\Delta^{++} \pi^{-}$
c) $\mathrm{N}^{\text {to }} \pi^{+}$
d) $\mathrm{p} \rho$
e) 3 uncorrelated particles.

Case a) has already been discussed. For incoherent decay we formulate the same hypothesis used to write the effective mass distribution (11). So we have:

$$
\begin{align*}
& \mathrm{f}\left(\mathrm{E}_{1} \mathrm{E}_{2} \mathrm{~W}\right)=\beta \mathrm{I}_{\rho}^{-1}\left|B_{\rho}\left(\mathrm{W}_{12}\right)\right|^{2} \mathrm{q}_{12}^{2}+\gamma\left|乃_{\Delta}\left(\mathrm{W}_{13}\right)\right|^{2} \mathrm{q}_{13}^{2} \mathrm{I}_{\Delta}^{-1}+ \\
& \quad+\lambda \mathrm{I}_{\mathrm{N}}^{-1}\left|B_{\mathrm{N}^{\circ *}}\left(\mathrm{~W}_{23}\right)\right|^{2} \mathrm{q}_{23}^{2}+\sigma \mathrm{I}_{\mathrm{F}}^{-1}\left(\mathrm{E}_{1}+\mathrm{E}_{2}-2 \mathrm{~m}_{\pi}\right)\left(\mathrm{W}-\mathrm{E}_{1}-\mathrm{E}_{2}\right) \tag{21}
\end{align*}
$$

where

$$
\mathrm{I}_{\rho}=\int \mathrm{dE}_{1} \mathrm{dE}_{2}\left|B_{\rho}\left(\mathrm{W}_{12}\right)\right|^{2} \mathrm{q}_{12}^{2}
$$

with similar expressions for $I_{\Delta}, I_{N}, I_{F}$.
The $\mathrm{q}_{12}$ is the two pions momentum in the $P$ CMS, $\mathrm{q}_{13}$ and $\mathrm{q}_{23}$ are defined in a similar way. One can express them as functions, respectively, of ${ }^{1} W_{12}, W_{13}, W_{23}$. The coefficients $\beta, \gamma, \lambda, \sigma$ are real and positive parameters, with

$$
\begin{equation*}
\beta+\gamma+\lambda+\sigma=1 \tag{22}
\end{equation*}
$$

In conclusion, taking into account the conditions (16), (17), (19), (20), (22) we have defined a Dalitz plot density distribution with 7 free parameters.

## 4. - CONCLUSION. -

We have seen some different tests to be applied to the $\pi^{+} \pi^{-} p$ system and in particular to the $N^{\star}(1700)$ resonance. Now let us briefly discuss the advantages and the limitations of each method,

As we have seen, the $I(\theta, \varphi)$ in (8), or the integrated distributions $I(\theta)$ and $I(\varphi)$, allows us to determine, in principle, both the spin and the density matrix elements of the $\mathrm{N}^{\mathrm{t}}(1700)$. The moments method looks more sure than the fitting method, as in that case we only take the average values of some angular functions (ex. the Legendre functions). However, the first method presen ted in sect. 2.3 seems to be the most effective, since we need not consider the integrated distributions (we have only $2 J+3$ parameters) : when we fit the $I(\theta)$, we neglect the $\varphi$ dependence and the parameters so determined are probably not best to fit the $I(\theta, \varphi)$. Last, we have purposed the Dalitz plot analysis, in connection with the latter method in sect. 2.3, as an alternative way to determine the spin for the $\mathrm{N}^{\mathbf{Z}}$. This analysis, which generally does not seem to be appreciated in studying the $\mathrm{N}^{\star}$, has some advantages. First, we can also determine the decay modes; second ly, expression (15) is independent of the production process; and last, if we consider more than one partial wave $J$, we have no interference terms ${ }^{(29)}$.

## ACKNOWLEDGEMENTS. -

I am grateful to C. Caso, E. Eberle and D. Teodoro for their indications and for the useful discussions I had with them.

## APPENDIX. -

Zemach ${ }^{(34)}$ gives the following formula for contraction of tensors :

$$
T^{J}(\vec{p}): T^{J^{\star}}(\vec{q})=\frac{C_{L} q^{L} p^{L}}{2 L+1}\left[(L+1) p_{L}(x)-i \vec{\sigma} \cdot \vec{p} \wedge \vec{q} p_{L}^{\prime}(x)\right]
$$

If we follow the differential technique suggested in the same reference, we obtain, by substituting $\overrightarrow{\mathrm{q}} \rightarrow \overrightarrow{\mathrm{q}}+\overrightarrow{\mathrm{a}}$

$$
\begin{aligned}
T^{J}(\vec{p}) & :\left[T^{J}(\vec{q})+L T^{J}(\vec{q} \ldots \vec{q} \vec{a})+\ldots\right]^{*}=\frac{C_{L^{\prime}} p^{L} q^{L}}{2 L+1}\left\{1+L \frac{\hat{q} \cdot \vec{a}}{q}+\ldots\right\} \\
& \cdot\left\{(L+1)\left[p_{L}(x)+d x p_{L}^{\prime}(x)\right]-i(\vec{\sigma} \cdot \vec{p} \wedge \vec{q})\left[p_{L}^{\prime}(x)+d x p_{L}^{\prime \prime}(x)\right]\right\}
\end{aligned}
$$

where $d x=(\hat{p} \cdot \vec{a}-x \hat{q} \cdot \vec{a}) \cdot \frac{1}{q}$.
Now, if we compare the coefficients of $\vec{a}$ in the r.h.s. and 1.h.s. of the equation, we have :

$$
\begin{aligned}
T^{J}(\vec{p}) & : T^{J}(\vec{q} \ldots \vec{q} \vec{a})=\frac{\hat{q} \cdot \vec{a}}{q} T^{J}(\vec{p}): T^{J}(\vec{q})+\frac{C_{L} p^{L} q^{L}}{L(2 L+1)}\left\{(L+1) p_{L}^{\prime}(x) d x+\right. \\
& \left.+i \vec{\sigma}\left[\left(\hat{p} \wedge \frac{\vec{a}}{q}-\frac{\hat{q} \cdot \vec{a}}{q} \hat{p} \wedge \hat{q}\right) p_{L}^{\prime}(x)+\hat{p} \wedge \hat{q} p_{L}^{\prime \prime}(x) d x\right]\right\} .
\end{aligned}
$$

In a similar way we can substitute $\vec{p} \rightarrow \vec{p}+\vec{b}$ in the last expression, obtaining

$$
T^{J}(\vec{p} \ldots \vec{p} \vec{b}): T^{J}(\vec{q} \ldots \vec{q} \vec{a})=\frac{\hat{q} \cdot \vec{a}}{q}\left\{\frac{\hat{p} \cdot \vec{b}}{p} T^{J}(\vec{p}): T^{J}(\vec{q})+\frac{C_{L} p^{L} q^{L}}{L(2 L+1)}\left[(L+1) p_{L}^{\prime}(x) d y-\right.\right.
$$

12. 

$$
\begin{aligned}
& \left.-i \vec{\sigma}\left(\frac{\vec{b}}{p} \wedge \hat{q}-\frac{\hat{p} \cdot \vec{b}}{p} \hat{p} \wedge \hat{q}\right) p_{L}^{\prime}(x)-i \vec{\sigma} \cdot \hat{p} \wedge \hat{q} p_{L}^{\prime \prime}(x) d y\right]+\frac{C_{L} p^{L} q^{L}}{L(2 L+1)} \frac{\hat{p} \cdot \vec{b}}{p} \\
& -\left[(L+1) p_{L}^{\prime}(x) d x-i \vec{\sigma}\left(\hat{p} \wedge \frac{\vec{a}}{q}-\frac{\hat{q} \cdot \vec{a}}{q} \hat{p} \wedge \hat{q}\right) p_{L}^{\prime}(x)-i \vec{\sigma} \cdot \hat{p} \wedge \hat{q} p_{L}^{\prime \prime}(x) d x\right]+ \\
& +\frac{C_{L^{p}} L^{L} q^{L}}{L^{2}(2 L+1)}\left\{( L + 1 ) \left[p_{L}^{\prime \prime}(x) d x d y+p_{L}^{\prime}(x) \delta(d x)-i \vec{\sigma}\left[\frac{\vec{b} \wedge \vec{a}}{p q}-\frac{(\hat{p} \cdot \vec{b}) \hat{p} \wedge \vec{a}}{p q}-\right.\right.\right. \\
& \left.-\frac{\hat{q} \cdot \vec{a}}{p q}(\vec{b} \wedge \hat{q}-(\hat{p} \cdot \vec{b}) \hat{p} \wedge \hat{q})\right] p_{L}^{\prime}(x)+i \vec{\sigma}\left(\frac{\hat{p} \wedge \vec{a}}{q}-\frac{\hat{q} \cdot \vec{a}}{q} \hat{p} \wedge \hat{q}\right) p_{L}^{\prime \prime}(x) d y- \\
& \left.-i \vec{\sigma}\left(\frac{\vec{b}}{p}-\frac{\vec{b} \cdot \hat{p}}{p} \hat{p}\right) \wedge \hat{q} p_{L}^{\prime \prime}(x) d x-i \vec{\sigma} \cdot \hat{p} \wedge \hat{q}\left[p_{L}^{\prime \prime}(x) \delta(d x)+p_{L}^{\prime \prime \prime}(x) d x d y\right]\right\}
\end{aligned}
$$

where

$$
\begin{aligned}
& d y=(\hat{q} \cdot \vec{b}-x \hat{p} \cdot \vec{b}) \frac{1}{p} \\
& \delta(d x)=\frac{1}{p q}[\vec{b} \cdot \vec{a}-(\hat{p} \cdot \vec{b})(\hat{p} \cdot \vec{a})-(\hat{q} \cdot \vec{a}) p d y] .
\end{aligned}
$$

Note that in the text we have omitted all $\sigma_{i}$ terms, because they wanish when we sum over the helicities of all the final protons:

$$
\sum_{\mathrm{m}} \overline{\mathrm{u}}(\mathrm{~m}) \sigma_{i} u(\mathrm{~m})=\operatorname{tr} \sigma_{i}=0 .
$$

By successively applying the differential technique, we can calculate every mixed term of the type

$$
T^{J}\left(p^{(1)} \ldots p^{(k)} q \ldots q\right): T^{J}\left(p^{(1)} \ldots p^{(r)} q \ldots q\right) .
$$
