L. Lovitch and S. Rosati : ON THE CORRECTOR FORMULAS FOR THE NUMERICAL SOLUTION OF THE SCHRÖDINGER EQUA TION FOR CENTRAL FIELDS.
L. Lovitch, S. Rosati: ON THE CORRECTOR FORMULAS FOR THE NUMERICAL SOLUTION OF THE SCHRÖDINGER EQUATION FOR CENTRAL FIELDS. -

The evaluation of the eigenvalues and corresponding solutions of a Schrodinger equation is an ever-present problem in atomic and nuclear physics. For the numerical evaluation of the Schrödinger equation for a par ticle in a central potential, a useful corrector formula was derived by Dou glas and Ridley ${ }^{(1)}$ some years ago. Given afirst estimate of the eigenvalue, this formula enables one to obtain a better estimate using any standard inte gration procedure for the differential equation. In a particular example, it was found ${ }^{(1)}$ that it was necessary to start with an initial value which was accurate to about $10 \%$ in order that the procedure converge to the desired eigenvalue, and that few iterations were required to obtain the eigenvalue with good precision.

More recently Cooley ${ }^{(2)}$ has obtained a quite similar corrector formula by applying to the problem a general matrix technique developed by Lowdin (3), using the Numerov formula for the numerical integration of the radial Schrödinger equation

$$
\begin{align*}
\frac{d^{2} y}{d r^{2}} & =\frac{2 \mu}{\hbar^{2}}[V(r)-E] y  \tag{1}\\
& =[v(r)-\varepsilon] y
\end{align*}
$$

If we divide the range of integration into equal steps of length $h$, the Nume rov recurrence relation is given by (see ref. (4))

$$
\begin{equation*}
z_{i+1}=2 z_{i}-z_{i-1}+h^{2} f_{i} y_{i} \tag{2}
\end{equation*}
$$

where we have written

$$
\begin{equation*}
f(r)=v(r)-\varepsilon, \tag{3}
\end{equation*}
$$

and

$$
\begin{equation*}
z=\left(1-\frac{h^{2}}{12} f\right) y \tag{4}
\end{equation*}
$$

With reference to the Douglas-Ridley corrector formula, both Hartree ${ }^{(4)}$ and Cooley ${ }^{(2)}$ state that this formula gives first-order convergen ce in correcting an approximate eigenvalue, that is to say, the true correc tion differs from the estimated correction by an amount proportional to the latter. If we look at how the Cooley corrector formula has been derived ${ }^{(2)}$, it is clear that it yields quadratic convergence in the correction of the eigen value: the eigenvalue is the zero of a certain function and the corrector for mula is the Newton-Raphson expression for improving an estimate of the ze ro of that function.

Here we want to show that the Douglas-Ridley corrector formula has really a quadratic convergence and that the Cooley formula may be deri ved directly from it.

In solving the Schrödinger equation numerically, for stability rea sons it is convenient to perform the integration in two steps: choosing a tria $\overline{1}$ eigenvalue;, eq. (1) is integrated outward from the origin and inward from large distances respectively, so as to satisfy the boundary conditions

$$
\begin{array}{ll}
\mathrm{y}=0, & \mathrm{r}=0, \\
\mathrm{y} \rightarrow 0, & \mathrm{r} \rightarrow \infty . \tag{5}
\end{array}
$$

Where the two solutions meet, at $r=R$ say, their logarithmic derivatives are equal if and only if the trial energy value coincides with one of the eigen values. And so, the eigenvalues are zeros of the difference of the logarithmic derivatives at $r=R$, regarded as a function of energy.

Consider the solutions $\mathrm{y}(\varepsilon), \mathrm{y}(\varepsilon+\delta \varepsilon)$ corresponding to values $\Sigma$ and $\varepsilon+\delta \varepsilon$ of the energy, i. e.

$$
\mathrm{y}^{\prime \prime}(\varepsilon)=(\mathrm{v}-\varepsilon) \mathrm{y}(\varepsilon)
$$

and

$$
\begin{equation*}
\mathrm{y}^{\prime \prime}(\varepsilon+\delta \varepsilon)=(\mathrm{v}-\varepsilon-\delta \varepsilon) \mathrm{y}(\varepsilon+\delta \varepsilon), \tag{6}
\end{equation*}
$$

where the primes denote derivation with respect to the radial coordinate r . It follows that

$$
\begin{equation*}
y(\varepsilon) y^{\prime}(\varepsilon+\delta \varepsilon)-\left.y(\varepsilon+\delta \varepsilon) y^{\prime}(\varepsilon)\right|_{r=a} ^{b}=-\delta \varepsilon \int_{r=a}^{b} \operatorname{dr} y(\varepsilon) y(\varepsilon+\delta \varepsilon) \tag{7}
\end{equation*}
$$

Let us "normalise" the outward and inward solutions so that they all pass through the same value $y_{m}$ at $r=R$. From eq. (7) we get, at $r=R$,

$$
\begin{gather*}
\frac{\mathrm{y}_{\text {out }}^{\prime}(\varepsilon+\delta \varepsilon)}{\mathrm{y}_{\text {out }}(\varepsilon+\delta \varepsilon)}=\frac{\mathrm{y}_{\text {out }}^{\prime}(\varepsilon)}{\mathrm{y}_{\text {out }}(\varepsilon)}-\frac{\delta \varepsilon}{\mathrm{y}_{\text {out }}(\varepsilon) \mathrm{y}_{\text {out }}(\varepsilon+\delta \varepsilon)} \int_{0}^{\mathrm{R}} \mathrm{dr}  \tag{8.1}\\
\cdot \mathrm{y}_{\text {out }}(\varepsilon) \mathrm{y}_{\text {out }}(\varepsilon+\delta \varepsilon)
\end{gather*}
$$

and

$$
\begin{gather*}
\frac{y_{i n}^{\prime}(\varepsilon+\delta \varepsilon)}{y_{\text {in }}(\varepsilon+\delta \varepsilon)}=\frac{y_{i n}^{\prime}(\varepsilon)}{y_{i n}(\varepsilon)}+\frac{\delta \varepsilon}{y_{i n}(\varepsilon) y_{i n}(\varepsilon+\delta \varepsilon)} \\
\cdot \int_{0}^{\infty} \operatorname{dr} y_{\text {in }}(\varepsilon) y_{\text {in }}(\varepsilon+\delta \varepsilon) \tag{8.2}
\end{gather*}
$$

and so

$$
\begin{align*}
& \frac{\mathrm{y}_{\text {out }}^{\prime}(\varepsilon+\delta \varepsilon)}{\mathrm{y}_{\text {out }}(\varepsilon+\delta \varepsilon)}-\frac{\mathrm{y}^{\prime}{ }_{\text {in }}\left(\varepsilon+\delta^{\prime} \varepsilon\right)}{\mathrm{y}_{\text {in }}(\varepsilon+\delta \varepsilon)}=\frac{\mathrm{y}^{\prime}{ }_{\text {out }}(\varepsilon)}{\mathrm{y}_{\text {in }}(\varepsilon)}-\frac{\mathrm{y}^{\prime}{ }_{\text {in }}(\varepsilon)}{\mathrm{y}_{\text {in }}(\varepsilon)}- \\
& -\frac{\delta \varepsilon}{\bar{y}_{\mathrm{m}} \bar{T}^{2}}\left\{\int_{0}^{\mathrm{R}} \mathrm{dr} \mathrm{y}_{\text {out }}(\varepsilon) \mathrm{y}_{\text {out }}(\varepsilon+\delta \varepsilon)+\int_{\mathrm{R}}^{\infty} \mathrm{dr}_{\mathrm{on}}(\varepsilon) \mathrm{y}_{\text {in }}(\varepsilon+\delta \varepsilon)\right\} \text {. } \tag{9}
\end{align*}
$$

If $\varepsilon$ is a trial eigenvalue, then the required eigenvalue $(\varepsilon+\delta \varepsilon)$ corresponds to the vanishing of the left-hand-side of (9), so that

$$
\begin{equation*}
\delta \varepsilon=\frac{\left.L y_{\text {out }}^{\prime}(\varepsilon)-y^{\prime}{ }_{\text {in }}(\varepsilon)-\right]_{\mathrm{m}}}{\int_{\text {o }}^{\mathrm{d}} \mathrm{dr}_{\mathrm{out}}(\varepsilon) \mathrm{y}_{\text {out }}(\varepsilon+\delta \varepsilon)+\int_{\mathrm{R}}^{\infty} \mathrm{dr} \mathrm{y}_{\text {in }}(\varepsilon) \mathrm{y}_{\text {in }}(\varepsilon+\delta \varepsilon)} \tag{10}
\end{equation*}
$$

This formula is exact and for numerical applications one may approximate it by the expression

$$
\begin{equation*}
\delta \varepsilon \simeq \frac{L \mathrm{y}_{\text {out }}^{\prime}(\Sigma)-\mathrm{y}_{\text {in }}^{\prime}(\Sigma)-\overline{/} \mathrm{y}_{\mathrm{m}}}{\int_{0}^{\mathrm{R}} \mathrm{dr}\left[\mathrm{y}_{\text {out }}(\Sigma) /^{2}+\int_{\mathrm{R}}^{\infty} \mathrm{dr}\left[\mathrm{y}_{\text {in }}(\Sigma)-/^{2}\right.\right.} \tag{11}
\end{equation*}
$$

which clearly has an error $0\left[(\delta \varepsilon)^{2}\right.$ _/. The expression (11) coincides with the Douglas-Ridley corrector formula, which has therefore quadratic convergence.

The deduction of the Cooley corrector formula from (11) is quite straightforward. Taking two points symmetrically situated at a distance $h$ from the point $r=R$, we have

$$
\begin{equation*}
\mathrm{y}_{\text {out }, \mathrm{m}-1}=\sum_{\mathrm{k}=0}^{\infty} \frac{(-\mathrm{h})^{\mathrm{k}}}{\mathrm{k}!} \mathrm{y}_{\text {out }, \mathrm{m}}^{(\mathrm{k})} \tag{12,1}
\end{equation*}
$$

and

$$
\begin{equation*}
y_{i n, m+1}=\sum_{k=0}^{\infty} \frac{h^{k}}{k!} y_{i n, m}^{(k)} \tag{12.2}
\end{equation*}
$$

Since $y_{m, \text { in }}=y_{m, \text { out }}=y_{m}$ and $y_{m, \text { in }}^{(2)}=y_{m}^{(2)}$, out (the latter is a consequence
4.
of the Schrödinger equation), it follows that

$$
\begin{align*}
& y_{\text {out, } m^{\prime}-y_{\text {in, } m}^{\prime}=h^{-1} L-y_{\text {out, } m-1}-y_{\text {in }, m+1}+2 y_{m}+h^{2} y_{m}^{(2)}} \\
& -\frac{h^{3}}{6} y_{\text {out }, \mathrm{m}}^{(3)}+\frac{h^{3}}{6} y_{\text {in, } m}^{(3)}+\frac{h^{4}}{24} y_{\text {out, } m}^{(4)}+\frac{h^{4}}{24} y_{\text {in }, \mathrm{m}}^{(4)}+0\left(\mathrm{~h}^{5}\right) \_/ \tag{13}
\end{align*}
$$

Using eq. (4) and

$$
\begin{equation*}
y^{(3)}=f^{\prime} y+f y^{\prime}, \tag{14}
\end{equation*}
$$

it follows that

$$
\begin{aligned}
y_{\text {out, } m}^{\prime}-y_{\text {in, } m}^{\prime} & =h^{-1} L-z_{\text {out, } m-1}-z_{\text {in }, m+1}+2 z_{m}+h^{2} f_{m} y_{m}- \\
& \left.-\frac{h^{3}}{12} f_{m}\left(y_{\text {out, } m}^{\prime}-y_{\text {in, }}^{\prime}\right)+0\left(h^{5}\right) \_\right]
\end{aligned}
$$

hence

$$
\begin{gather*}
\left(1+\frac{h^{2}}{12} f_{m}\right)\left(y_{\text {out, } m}^{\prime-y^{\prime}}{ }_{\text {in }, m}\right)=h^{-1} L^{-z_{\text {out }, m-1}-z_{i n, m+1}+2 z_{m}+} \\
+h^{2}{ }_{f_{m}} y_{m}-/+0\left(h^{4}\right) . \tag{15}
\end{gather*}
$$

Eq. (11) therefore becomes

$$
\begin{align*}
\delta \varepsilon & \simeq \frac{h^{-1} y_{m} L-z_{\text {out }, m-1}^{-z_{i n}, m+1}+2 z_{m}+h^{2} f_{m} y_{m-} /}{\left(1+\frac{h^{2}}{12} f_{m}\right)\left\{\int_{0}^{R} d r y_{\text {out }}^{2}+\int_{R}^{\infty} d r y_{i n}^{2}\right\}}+0\left(h^{4}\right) \\
& =\frac{h^{-1} z_{m} L^{-} z_{\text {out }, m-1}^{-z}{ }_{\text {in }, m+1}^{+2 z_{m}+h^{2} f_{m} y_{m-} /}}{\int_{0}^{R} d r y_{\text {out }}^{2}+\int_{R}^{\infty} d r y_{\text {in }}^{2}}+0\left(h^{4}\right) . \tag{16}
\end{align*}
$$

The Cooley corrector formula is given by the latter expression with the integrals of the denominator approximated by the simple trapezoidal integration formula.

An extension of the preceding method in the research of the poten tial of a given analytic form which best reproduces a set of experimental dā ta is in progress.
