G. Cattapan and V. Vanzani : OFF-SHELL EFFECTS IN NUCLEON-EXCHANGE REACTIONS.

SUMMARY. -
Nucleon-nucleus rearrangement reactions proceeding via a nu-cleon-exchange mechanism are investigated in the framework of a three-body model. Starting from the Alt, Grassberger and Sandhas representation for the transition operators, we derive, by means of a suitable operator multiplier technique, an uncoupled integral equa tion showing in the inhomogeneous term the role of the nucleon-nucleon off-energy-shell t-matrix. The knock-out triangular diagram amplitude involving the off-energy-shell t-matrix is compared with the corresponding amplitude in the Born approximation for the t-ma trix. Our results show that the knock-out amplitude is rather sensitive to the off-shell behaviour of the two-nucleon interactions.

## 1. - INTRODUCTION. -

Since the Faddeev work on the three-body problem ${ }^{(1)}$ a great deal of theoretical interest has been devoted to the off-shell aspects of the nuclear interactions. Indeed, the off-shell behaviour of the two-body scattering amplitudes represents the input information for solving problems that involve composite particles.

Nuclear rearrangement reactions are possible tools to explore in detail the role of these off-shell effects. For an exact description, the rearrangement scattering problem should be formulated in a N --body context $(\mathrm{N} \geq 3)^{(2,3)}$. Generally, for $\mathrm{N}>3$ this treatment ap pears to be too complicate for practical purposes. For this reason,
one usually limits oneself to processes which can be approximately treated in three-body context. Among them we choose, as testing ground for investigating off-shell effects, the nucleon-nucleus rearrangement reactions proceeding via a nucleon-exchange mechanism.

Our choice is motivated by three main features relative to the theoretical description of such a rearrangement problem. First, to construct the inhomogeneous term of the uncoupled integral equation with compact kernel for the rearrangement scattering operator, one needs only the nucleon-nucleon off-shell $t$-matrix, which has been extensively studied in the last years and, therefore, is fairly well known. Second, the transition amplitude contains nucleon-nucleus form factors which are simpler, and therefore better known than the nucleus-nucleus ones involved in transfer reactions between two nuclei. Third, from a study of the Feynman diagrams associated with the possible reaction mechanisms ${ }^{(4)}$, it follows that the off-shell be haviour would affect predominantly the cross sections in the forward angle region, where they are larger and therefore better known than the backward region values. On the contrary, in stripping and pick-up reactions similar off-shell effects predominate at backward angles.

We have been stimulated to study the above off-shell effects al so by some suggestions coming from earlier studies on the effective interaction in nucleon-nucleus scattering problem $(5,6)$. There one recognizes that the effective interaction, responsible for the transition, has the nature of a transition operator. In the spirit of the usual distorted-wave Born approximation (DWBA) only the Born term of the transition operator is retained ${ }^{(7)}$. To get a first insight into the role of the $t$-matrix it was assumed that the off-shell $t$-matrix had the same form as the free on-shell transition matrix ${ }^{(8)}$. However, it has been proved that this on-shell approximation is not generally adequate, e. g. for break-up reactions below $150-200 \mathrm{MeV}^{(9,10,11)}$.

The importance of the nucleon-nucleon off-energy-shell effects in the nucleon-exchange reactions has been already outlined, from a qualitative point of view, within the context of the static limit model for the three-body problem(12). To give a quantitative evaluation for them, we shall compare calculations involving the two-nucleon off--shell t-matrix with calculations involving only its Born approximation.

In order to clarify the role of the nucleon-nucleon t-matrix in the framework of a three-body approach, we shall outline an alternative procedure to the usual Faddeev-Lovelace method ${ }^{(1,13-15)}$. By means of a suitable operator multiplier technique $(16,17)$, we obtain one uncoupled integral equation with a compact kernel. The inhomogeneous term, which corresponds, in the Feynman diagram language ${ }^{(18)}$, to the sum of a heavy-particle stripping polar graph and a
knock-out triangular graph, will be rewritten in a compact form involving the Green function for the two-nucleon subsystem.

In a three-body context one can construct a generalized distor ted-wave model which has the above inhomogeneous term as starting point and is completely equivalent to the Feynman diagram summation method (FDSM) ${ }^{(4,19-22)}$. Unfortunately, the simultaneous use of the off-shell t-matrix and of the distorted-waves requires a prohi bitive amount of computing time, because of the high-dimensional na ture of the integrals involved and of the required transformations in the momentum-space between the arguments of the t-matrix and those of the distorted-waves.

Therefore, we shall resort to the approximate treatment propo sed in a recent work on the off-shell effects in break-up reactions (1I, x) According to this paper, we limit ourselves to evaluate the two-nucleon t-matrix operator between asymptotic channel states in the for ward scattering angle region and for not too low energies. In these cases one expects that the first terms of the Watson-Faddeev multiple scattering series ${ }^{(23)}$ are responsible for the leading behaviour of the transition amplitude ${ }^{(24)}$.

According to earlier calculations concerning different nuclear reactions, our results show that the knock-out amplitude for nucleon--exchange reactions is rather sensitive to the off-energy-shell behaviour of the two-nucleon t-matrix in the energetic range usually explored in experiments. By comparing the off-energy-shell t-matrix calculations with the Born ones, we find a relevant difference in the absolute magnitude of the cross sections, while the shapes of the angular distributions are almost the same in both cases.

Section 2 deals with a general three-body formulation of nucleon--exchange reactions in terms of symmetric transition operators. Section 3 is devoted to the knock-out triangular diagram amplitude involv ing the neutron-proton off-energy-shell $t$-matrix. A convenient regularization procedure is carried out in order to evaluate numerically some singular integrals. In Section 4 we shall be concerned with the comparison between the off-energy-shell t-matrix calculations and the corresponding Born ones,

[^0]4.

## 2. - GENERAL THREE-BODY APPROACH IN TERMS OF SYMMETRIC TRANSITION OPERATORS. -

2.1. - Formalism.

Nucleon-nucleus rearrangement processes $A(a, b) B$ proceeding via an exchange between the incident nucleon a and a nucleon $b$ of the target can be written schematically as

$$
\begin{equation*}
a+(b+c) \rightarrow b+(a+c), \tag{2.1}
\end{equation*}
$$

where $c$ is the core both of the target nucleus $A=b+c$ and of the residual nucleus $B=a+c(a, b=p, n ; a \neq b)$.

We describe the reaction (2.1) by means of a three-body model. The nuclear cluster $c$ is treated as an inert core.

We start from the nonstandard symmetric form for the transition operators $\left(\bar{\delta}_{\beta \alpha}=1-\delta_{\beta \alpha}\right)$

$$
\begin{align*}
& \mathrm{U}_{\beta \alpha}(\mathrm{z})=\bar{\delta}_{\beta \alpha} \mathrm{G}_{\alpha}^{-1}(\mathrm{z})+\mathrm{V}_{\beta}+\mathrm{V}_{\beta} \mathrm{G}(\mathrm{z}) \mathrm{V}_{\alpha},  \tag{2.2a}\\
& \mathrm{U}_{\beta \alpha}(\mathrm{z})=\bar{\delta}_{\beta \alpha} \mathrm{G}_{\beta}^{-1}(\mathrm{z})+\mathrm{V}_{\alpha}+\mathrm{V}_{\beta} \mathrm{G}(\mathrm{z}) \mathrm{V}_{\alpha}, \tag{2.2b}
\end{align*}
$$

proposed by Alt, Grassberger and Sandhas ${ }^{(14)}$. The indices $\alpha$ and $\beta$ denote the unbound particle ( $\alpha, \beta=\mathrm{a}, \mathrm{b}, \mathrm{c}$ ) in the initial and final chan nel, respectively, or the asymptotic state with all particles free ( $\alpha$, $\beta=0$ ). The operator $V_{\alpha}$ represents the sum of the interactions not contained in the channel $\alpha$, that is $\mathrm{V}_{\alpha}=\mathrm{V}-\mathrm{v}_{\alpha}$, where V is the sum of all the interactions and $\mathrm{v}_{\alpha}$ the interaction between $\beta$ and $\gamma$ $\left(\alpha \neq \beta \neq \gamma ; \mathrm{v}_{\mathrm{O}}=0\right)$. The resolvent operators are defined as usual

$$
\begin{equation*}
\mathrm{G}_{\alpha}(\mathrm{z})=\left(\mathrm{z}-\mathrm{H}_{\alpha}\right)^{-1}, \quad \mathrm{G}(\mathrm{z})=(\mathrm{z}-\mathrm{H})^{-1} \tag{2,3}
\end{equation*}
$$

where $\mathrm{H}_{\alpha}$ and H are the channel and the total Hamiltonian, respectively. The two-body scattering operators $\mathrm{t}_{\alpha}$, acting in the three-par ticle space and satisfying the well-known equations

$$
\begin{equation*}
\mathrm{t}_{\alpha}(\mathrm{z})=\mathrm{v}_{\alpha}+\mathrm{v}_{\alpha} \mathrm{G}_{\mathrm{o}}(\mathrm{z}) \mathrm{t}_{\alpha}(\mathrm{z})=\mathrm{v}_{\alpha}+\mathrm{t}_{\alpha}(\mathrm{z}) \mathrm{G}_{\mathrm{o}}(\mathrm{z}) \mathrm{v}_{\alpha}, \tag{2.4}
\end{equation*}
$$

are connected with the above channel resolvents by the relations

$$
\begin{equation*}
\mathrm{G}_{\alpha}(\mathrm{z})=\mathrm{G}_{\mathrm{o}}(\mathrm{z})+\mathrm{G}_{\mathrm{o}}(\mathrm{z}) \mathrm{t}_{\alpha}(\mathrm{z}) \mathrm{G}_{\mathrm{o}}(\mathrm{z}) . \tag{2.5}
\end{equation*}
$$

The transition operators (2.2) coincide on-the-energy-shell with
the conventional asymmetrical ones

$$
\begin{align*}
& \mathrm{U}_{\beta \alpha}^{-}(\mathrm{z})=\mathrm{V}_{\alpha}+\mathrm{V}_{\beta} \mathrm{G}(\mathrm{z}) \mathrm{V}_{\alpha},  \tag{2.6a}\\
& \mathrm{U}_{\beta \alpha}^{+}(\mathrm{z})=\mathrm{V}_{\beta}+\mathrm{V}_{\beta} \mathrm{G}(\mathrm{z}) \mathrm{V}_{\alpha}, \tag{2.6b}
\end{align*}
$$

and therefore give, in the asymptotic channel state representation, the physical transition amplitudes.

We shall introduce in Sect, 2. 2 a suitable operator multiplier technique, by starting from the Lippmann-Schwinger (LS) equations for the symmetric transition operators (2.2)

$$
\begin{equation*}
\mathrm{U}_{\beta \alpha}(\mathrm{z})=\bar{\delta}_{\beta^{\alpha}} \mathrm{G}_{\alpha}^{-1}(\mathrm{z})+\delta_{\beta \alpha^{\alpha}} \mathrm{V}_{\alpha}+\mathrm{V}_{\beta} \mathrm{G}_{\beta}(\mathrm{z}) \mathrm{U}_{\beta}{ }^{(\mathrm{z})}, \tag{2.7a}
\end{equation*}
$$

$$
\begin{equation*}
\mathrm{U}_{\beta \alpha}(\mathrm{z})=\bar{\delta}_{\beta \alpha} \mathrm{G}_{\beta}^{-1}(\mathrm{z})+\delta_{\beta \alpha} \mathrm{V}_{\beta}+\mathrm{U}_{\beta \alpha}(\mathrm{z}) \mathrm{G}_{\alpha}(\mathrm{z}) \mathrm{V}_{\alpha} . \tag{2.7b}
\end{equation*}
$$

Equations (2.7) have the same kernel as the LS equations for the con ventional operators (2.6)

$$
\begin{align*}
& \mathrm{U}_{\beta \alpha}^{-}(\mathrm{z})=\mathrm{V}_{\alpha}+\mathrm{V}_{\beta} \mathrm{G}_{\beta}(\mathrm{z}) \mathrm{U}_{\beta \alpha}^{-}(\mathrm{z}),  \tag{2.8a}\\
& \mathrm{U}_{\beta \alpha}^{+}(\mathrm{z})=\mathrm{V}_{\beta}+\mathrm{U}_{\beta \alpha}^{+}(\mathrm{z}) \mathrm{G}_{\alpha}(\mathrm{z}) \mathrm{V}_{\alpha},
\end{align*}
$$

but differ from them in the inhomogeneous term. It is well known that, owing to the noncompactness of their kernel, the LS equations are not amenable to a solution by usual calculational schemes.

Conventional approaches to nuclear rearrangement processes start, usually, from a Born approximation of the eqs. (2. 8) or of some more sophisticated equations (e. g. see eqs. $(34,35)$ of ref. (25)) hav ing, like the eqs. (2.8) a noncompact kernel. For instance, in the usual DWBA one assumes that the interaction responsible for the transition is given by the non-optical part of the inhomogeneous term of the eq. (2.8a) or (2.8b), i. e. by $V_{\alpha}-W_{\alpha}$ in the prior representation or by $\mathrm{V} \beta-\mathrm{W}_{\beta}$; in the post representation $\left(\mathrm{W}_{\alpha}\right.$ and $\mathrm{W}_{\beta}$ are the optical potentials in the initial and in the final channel respec tively) ${ }^{(26)}$. For the exchange or knock-out processes (2.1) on a heavy target nucleus one approximates $\mathrm{W}_{\alpha}$ by $\mathrm{v}_{\mathrm{b}}$ and $\mathrm{W}_{\beta}$ by $\mathrm{v}_{\mathrm{a}}$, so that the interaction causing the transition is assumed to be the potential $\mathrm{v}_{\mathrm{C}}$ between a and $b^{(7,12)}$.

A rigorous mathematical basis for deriving correct approxima tions to the exact transition amplitudes is provided by the Faddeev--Lovelace equations for the operators (2.2)(14). By iterating them once, one obtains integral equations characterized by a compact ker nel and exhibiting in their inhomogeneous term the two-body t-opera tors.
6.

## 2. 2. - An Operator-Multiplier Technique.

Integral equations with inhomogeneous terms involving two-body scattering operators can be directly derived from the LS equations in the general context of the operator multiplier techniques proposed by Blankenbecler and Sugar ${ }^{(16)}$. This alternative procedure to the Fad-deev-Lovelace one, appears more suggestive because it leads to uncoupled integral equations having at once a compact kernel without need of iteration. The multiplier we use for rearrangement processes $(\alpha \neq \beta)$ is slightly different from that proposed in ref. (17). Furthermore, it is applied to the symmetric transition operators and not to the conventional ones, as in ref. (17).

Let us multiply on the left hand side the eq. (2.7a) by the opera tor $(\alpha \neq \beta \neq \gamma, \quad \beta \neq 0)$

$$
\begin{equation*}
M_{\gamma \alpha}=\left(1-v_{\gamma} G_{o}\right)^{-1}\left(1-v_{\alpha} G_{o}\right)^{-1}, \tag{2.9a}
\end{equation*}
$$

which does not introduce spurious bound-state solutions ${ }^{(16,17)}$. Using the relations

$$
\begin{equation*}
\left(1+\mathrm{t}_{\alpha} \mathrm{G}_{\mathrm{o}}\right)\left(1-\mathrm{v}_{\alpha} \mathrm{G}_{\mathrm{o}}\right)=1, \quad \mathrm{G}_{\alpha} \mathrm{v}_{\alpha}=\mathrm{G}_{\mathrm{o}} \mathrm{t}_{\alpha}, \tag{2.10}
\end{equation*}
$$

the new inhomogeneous term reads

$$
\begin{equation*}
\mathrm{M}_{\gamma \alpha} \mathrm{G}_{\alpha}^{-1}=\mathrm{G}_{\mathrm{o}}^{-1} \mathrm{G}_{\gamma} \mathrm{G}_{\mathrm{o}}^{-1}=\mathrm{G}_{\mathrm{o}}^{-1}+\mathrm{t}_{\gamma} \tag{2.11}
\end{equation*}
$$

and coincides with the sum of the two simplest terms appearing in the iterated Faddeev-Lovelace equations for rearrangement processes. After some straightforward manipulations on the kernel of the eq. (2.7a) we obtain the following uncoupled integral equation with compact kernel

$$
\begin{equation*}
\mathrm{U}_{\beta \alpha}=\mathrm{G}_{\mathrm{o}}^{-1}+\mathrm{t}_{\gamma}+\left(1+\mathrm{t}_{\gamma} \mathrm{G}_{\mathrm{o}}\right)\left(1+\mathrm{t}_{\alpha} \mathrm{G}_{\mathrm{o}}\right)\left(\mathrm{v}_{\alpha} \mathrm{G}_{\mathrm{o}} \mathrm{v}_{\gamma}+\mathrm{v}_{\beta} \mathrm{G}_{\mathrm{o}} \mathrm{t}_{\beta}\right) \mathrm{G}_{\mathrm{o}} \mathrm{U}_{\beta \alpha} \tag{2.12}
\end{equation*}
$$

To eliminate the explicit appearance of the potentials in the kernel, the properties (2.10) should be used in a way similar to what is done in ref. (17). Multiplying on the right hand side the eq. (2. 7b) by the operator

$$
\begin{equation*}
L_{\beta \gamma}=\left(1-G_{o} v_{\beta}\right)^{-1}\left(1-G_{o} v_{\gamma}\right)^{-1} \tag{2.9b}
\end{equation*}
$$

one obtains an equation equivalent to (2.12) with the same inhomogeneous term ${ }^{(x)}$.
(x) - The inhomogeneous term (2.11) of the eq. (2.12) can also be direc tly obtained in the framework of the Yakubovskiil formalism applied to the three-body case ${ }^{(3)}$.

## 2. 3. - Polar and Triangular Diagram Mechanisms.

In the channel state representation $\left|\phi_{\alpha}\right\rangle$ the first term of eq. (2.12), which contributes only to rearrangement collisions, coincides on-the-energy-shell with the amplitude for the polar diagram describ ing the transfer of the particle $\gamma$ (Fig. 1a with $\dot{\gamma}=\mathrm{c}$ ). As far as the process (2.1) is concerned, one has

$$
\begin{align*}
& A_{p}=\left\langle\phi_{\mathrm{b}}\right| \mathrm{G}_{\mathrm{o}}^{-1}\left|\phi_{\mathrm{a}}\right\rangle=\left\langle\phi_{\mathrm{b}}\right| \mathrm{v}_{\mathrm{b}} \mathrm{G}_{\mathrm{o}} \mathrm{v}_{\mathrm{a}}\left|\phi_{\mathrm{a}}\right\rangle=\left\langle\phi_{\mathrm{b}}\right| \mathrm{v}_{\mathrm{b}}\left|\phi_{\mathrm{a}}\right\rangle=  \tag{2.13}\\
&=\left\langle\phi_{\mathrm{b}}\right| \mathrm{v}_{\mathrm{a}}\left|\phi_{\mathrm{a}}\right\rangle
\end{align*}
$$

(a)

(b)

FIG. 1 - Polar (a) and triangular (b) diagrams for the nucleon--exchange reaction (2.1).

These equalities follow from the homogeneous integral equation for two-body bound states. The second term in (2.12) gives in the channel state representation the amplitude for the triangular diagram describ ing a knock-out mechanism with $\alpha-\beta$ off-shell interactions (Fig. 1b with $\alpha=\mathrm{a}, \quad \beta=\mathrm{b}$ and $\gamma=\mathrm{c}$ ). One has

$$
\begin{equation*}
\mathrm{A}_{\mathrm{T}}=\left\langle\phi_{\mathrm{b}}\right| \mathrm{t}_{\mathrm{c}}\left|\phi_{\mathrm{a}}\right\rangle=\left\langle\phi_{\mathrm{b}}\right| \mathrm{v}_{\mathrm{b} \mathrm{G}_{\mathrm{oc}} \mathrm{t}_{\mathrm{o}} \mathrm{G}_{\mathrm{a}}}\left|\phi_{\mathrm{a}}\right\rangle . \tag{2.14}
\end{equation*}
$$

- Summing the amplitudes (2.13) and (2.14) and taking into account the relation (2.5) one obtains the following compact form for the inhomogeneous term in (2.12)

$$
\begin{equation*}
A_{p}+A_{T}=\left\langle\phi_{\mathrm{b}}\right| \mathrm{v}_{\mathrm{b}} \mathrm{G}_{\mathrm{c}} \mathrm{v}_{\mathrm{a}}\left|\phi_{\mathrm{a}}\right\rangle . \tag{2.15}
\end{equation*}
$$

Notice the explicit appearance of the resolvent operator $G_{c}$ for the a-b subsystem.

Obviously, the terms $G_{o}^{-1}$ and $t_{c}$ are the zero-order term and the first-order one, respectively, of the multiple-rearrangement scat tering series $(23,24)$ which can be derived from the Faddeev-Lovelace $\bar{e}$ equations for symmetric transition operators. They correspond to the simplest graphs for single-exchange reactions which can be obtained in the framework of the nonrelativistic Feynman-diagram approach to direct nuclear reactions ${ }^{(18)}$.

From the well-known expressions of the distance of the Feynman diagram singularities from the physical region boundaries, it follows that the triangular singularity dominates at forward angles, while the polar one contributes mainly in the backward direction. Furthermore, for nucleon-exchange on a heavy target nucleus, the triangular singularity is much nearer to the forward physical region boundary than the polar one to the backward boundary.

Notice that the polar and triangular graphs have the same three--ray vertex functions (i.e. the nucleon-nucleus form factors), the lat ter containing, furthermore, a four-ray vertex function (i.e. the two--nucleon off-shell t-matrix), which will be treated in Section 3.2.

Higher-order terms in the multiple-scattering series are expected to give contributions increasingly isotropic. This is borne out strongly by some calculations relative to a collision problem involving three-nucleons (see ref.(24)). Thus, the leading behaviour of the transition amplitude is given by the first terms in eq. (2.12).

Starting from the Faddeev-Lovelace equations for the symmetric transition operator, neglecting the coupling terms between elastic and rearrangement channels in the equations for the operators $\mathrm{U}_{\mathrm{aa}}$ and $\mathrm{U}_{\mathrm{bb}}{ }^{(22)}$, and taking into account only the channel bound state term $\left|\psi_{\alpha}>\mathrm{g}_{\alpha}<\psi_{\alpha}\right|$ in the spectral representation for $\mathrm{G}_{\alpha}(\alpha=\mathrm{a}, \mathrm{b})$, one obtains, on-the-energy-shell, the generalized distorted-wave approxi mation (GDWA) ${ }^{(4)}$

$$
\left\langle\phi_{\mathrm{b}}\right| \mathrm{U}_{\mathrm{ba}}^{\mathrm{GDWA}}\left|\phi_{\mathrm{a}}\right\rangle=
$$

$$
\begin{equation*}
\left.=\left\langle\overrightarrow{\mathrm{p}}_{\mathrm{b}}^{\prime} \mathrm{m}_{\mathrm{b}}^{\prime}\right|\left(1+\mathrm{u}_{\mathrm{bb}} \mathrm{~g}_{\mathrm{b}}\right)\left|\left\langle\psi_{\mathrm{b}}\right| \mathrm{v}_{\mathrm{b}} \mathrm{G}_{\mathrm{c}} \mathrm{v}_{\mathrm{a}}\right| \psi_{\mathrm{a}}\right\rangle\left(1+\mathrm{g}_{\mathrm{a}} \mathrm{u}_{\mathrm{aa}}\right)\left|\overrightarrow{\mathrm{p}}_{\mathrm{a}} \mathrm{~m}_{\mathrm{a}}\right\rangle, \tag{2.16}
\end{equation*}
$$

where $\overrightarrow{\mathrm{p}}_{\mathrm{a}}\left(\overrightarrow{\mathrm{p}}_{\mathrm{b}}^{\prime}\right)$ is the initial (final) channel momentum, $\mathrm{m}_{\alpha}$ the z-com ponent of the spin of the particle $\alpha,\left|\psi_{\alpha}\right\rangle$ the $\alpha$-channel bound state and $\left|\phi_{\alpha}\right\rangle=\left|\overrightarrow{\mathrm{p}}_{\alpha} \mathrm{m}_{\alpha}\right\rangle\left|\psi_{\alpha}\right\rangle$. The quantities $\mathrm{u}_{\alpha \alpha}=\left\langle\psi_{\alpha}\right| \mathrm{U}_{\alpha \alpha}\left|\psi_{\alpha}\right\rangle$ are the optical scattering operators acting on the plane-wave states $\left|\overrightarrow{\mathrm{p}}_{\alpha} \mathrm{m}_{\alpha}\right\rangle$. The wave-operators $1+\mathrm{g}_{\alpha} \mathrm{u}_{\alpha \alpha}$ operating on $\left|\overrightarrow{\mathrm{p}}_{\alpha} \mathrm{m}_{\alpha}\right\rangle$ give the effective two-body distorted-wave states ${ }^{(19)}$.

The operator $\mathrm{v}_{\mathrm{b}} \mathrm{G}_{\mathrm{c}} \mathrm{v}_{\mathrm{a}}$ sandwiched between the internal bound states in eq. (2.16) plays the role of a generalized transition potential. It corresponds to the inhomogeneous term of the eq. (2.12) (see also eq. (2.11)). If the three-particle intermediate state effects are ne$\operatorname{glected}^{(x)}$ and the a-b off-shell t-operator is replaced by its Born
(x) - This means to assume that the equality $\mathrm{G}_{\mathrm{o}} \mathrm{v}_{\alpha}\left|\psi_{\alpha}\right\rangle=\left|\psi_{\alpha}\right\rangle$ holds also off-the-energy-shell.
approximation, the eq. $(2,16)$ assumes the usual DWBA form for exchange reactions. For strong interactions it is unlikely that $\mathrm{v}_{\mathrm{c}}$ is always a good approximation to $t_{c}$. If the triplet deuteron bound state and the singlet virtual state are important in the intermediate state, the Born term is manifestly inadequate. Furthermore, the normalization of the DWBA depends on $\mathrm{v}_{\mathrm{C}}$ and it is, generally, different from the normalization based on $t_{c}$.

The GDWA (2.16) involves a nine-dimensional integral ${ }^{(22)}$. For the reasons explained in Sect. 1 and according to the ref. (11) we shall limit ourselves to evaluate the knock-out triangular diagram amplitude (2.14) with the off-energy-shell $t_{c}$-matrix contributions.

## 3. - THE KNOCK-OUT TRIANGULAR DIAGRAM AMPLITUDE. -

## 3.1. - General Form of the Knock-out Amplitude.

Let us now give an explicit evaluation of the knock-out triangular diagram amplitude (2.14) involving the off-shell $t_{c}$-matrix. Three--body states in momentum-space depend on the momentum pair $\overrightarrow{\mathrm{p}}_{\alpha}$ and $\overrightarrow{\mathrm{k}}_{\alpha}(\alpha=a, b, c)$, where $\overrightarrow{\mathrm{p}}_{\alpha}$ is the momentum of particle $\alpha$ in the total center of mass system, and $\overrightarrow{\mathrm{k}}_{\alpha}$ is the relative momentum between the particles $\beta$ and $\gamma^{(x)}$. In this representation three-particle states with all particles free will be denoted by $\left|\overrightarrow{\mathrm{k}}_{\alpha} \overrightarrow{\mathrm{p}}_{\alpha} \mathrm{m}_{\mathrm{a}} \mathrm{m}_{\mathrm{b}} \mathrm{m}_{\mathrm{c}}\right\rangle$. Omitting spin state specification, one has

$$
\begin{equation*}
\left|\overrightarrow{\mathrm{k}}_{\mathrm{a}} \overrightarrow{\mathrm{p}}_{\mathrm{a}}\right\rangle=\left|\overrightarrow{\mathrm{k}}_{\mathrm{b}} \overrightarrow{\mathrm{p}}_{\mathrm{b}}\right\rangle=\left|\overrightarrow{\mathrm{k}}_{\mathrm{c}} \overrightarrow{\mathrm{p}}_{\mathrm{c}}\right\rangle \tag{3.1}
\end{equation*}
$$

since they describe the same state. Different apices will be used to denote different three-body states.

Let us now insert in eq. (2.14) intermediate momentum integra tions and magnetic sums over the complete sets of two-body states $\left|\overrightarrow{\mathrm{k}}_{\mathrm{b}}^{\prime} \mathrm{m}_{\mathrm{a}}^{\prime} \mathrm{m}_{\mathrm{c}}^{\prime}\right\rangle$ and $\left|\overrightarrow{\mathrm{k}}_{\mathrm{a}} \mathrm{m}_{\mathrm{b}} \mathrm{m}_{\mathrm{c}}\right\rangle$, and take into account eq. (3.1) and the following relations between momenta specifying the same three-body state

$$
\begin{equation*}
\overrightarrow{\mathrm{k}}_{\mathrm{a}}=-\frac{\mathrm{M}_{\mathrm{c}}}{\mathrm{M}_{\mathrm{b}}+\mathrm{M}_{\mathrm{c}}} \overrightarrow{\mathrm{p}}_{\mathrm{a}}-\overrightarrow{\mathrm{p}}_{\mathrm{c}}, \quad \overrightarrow{\mathrm{k}}_{\mathrm{c}}=\frac{\mathrm{M}_{\mathrm{a}}}{\mathrm{M}_{\mathrm{a}}+\mathrm{M}_{\mathrm{b}}} \overrightarrow{\mathrm{p}}_{\mathrm{c}}+\overrightarrow{\mathrm{p}}_{\mathrm{a}} \tag{3.2}
\end{equation*}
$$

$$
\begin{equation*}
\overrightarrow{\mathrm{k}}_{\mathrm{b}}^{\prime}=\frac{\mathrm{M}_{\mathrm{c}}}{\mathrm{M}_{\mathrm{a}}+\mathrm{M}_{\mathrm{c}}} \overrightarrow{\mathrm{p}}_{\mathrm{b}}^{\prime}+\overrightarrow{\mathrm{p}}_{\mathrm{c}}^{\prime} ; \tag{3.3}
\end{equation*}
$$

$$
\overrightarrow{\mathrm{k}}_{\mathrm{c}}^{\prime}=-\frac{\mathrm{M}_{\mathrm{b}}}{\mathrm{M}_{\mathrm{a}}+\mathrm{M}_{\mathrm{b}}} \overrightarrow{\mathrm{p}}_{\mathrm{c}}^{\prime}-\overrightarrow{\mathrm{p}}_{\mathrm{b}}^{\prime},
$$

(x) - With the symbols $\overrightarrow{\mathrm{k}}_{\alpha}, \overrightarrow{\mathrm{p}}_{\alpha}$ we denote physical momenta and not the normalized ones, as in ref.(13). See the kinematic considerations developed in ref. (22).
10.
where $\mathrm{M}_{\alpha}$ is the mass of the particle $\alpha$. Changing the integration va riables $\overrightarrow{\mathrm{k}}_{\mathrm{b}}^{\prime}$ and $\overrightarrow{\mathrm{k}}_{\mathrm{a}}$ in $\overrightarrow{\mathrm{p}}_{\mathrm{c}}^{\prime}$ and $\overrightarrow{\mathrm{p}}_{\mathrm{C}}$, respectively, and expressing the $t_{c}$-matrix elements in the three-body space in terms of the $\hat{t}_{c}$-matrix elements in the $a-b$ two-body subspace, namely

$$
\begin{align*}
& \left\langle\vec{k}_{c}^{\prime} \vec{p}_{c}^{\prime} m_{a}^{\prime} m_{b}^{\prime} m_{c}^{\prime}\right| t_{c}(z)\left|\vec{k}_{c} \vec{p}_{c} m_{a} m_{b} m_{c}\right\rangle= \\
& \quad=\left\langle\vec{k}_{c}^{\prime} m_{a}^{\prime} \cdot m_{b}^{\prime}\right| \hat{t}_{c}\left(z-\frac{\not h^{2} p_{c}^{2}}{2 \nu_{c}}\right)\left|\vec{k}_{c} m_{a} m_{b}\right\rangle \delta\left(p_{c}^{\prime}-p_{c}\right) \delta_{m_{c}^{\prime} m_{c}} \tag{3.4}
\end{align*}
$$

one obtains

$$
\begin{equation*}
A_{T}=\sum_{b} m_{c} m_{a}^{\prime} \int \frac{f_{b}^{*}\left(\vec{q}_{b}^{\prime} m_{a}^{\prime} m_{c}\right)\left\langle\vec{q}_{c}^{\prime} m_{a}^{\prime} m_{b}^{\prime}\right| \hat{t}_{c}(S+i \gamma)\left|\vec{q}_{c} m_{a} m_{b}\right\rangle f_{a}\left(\vec{q}_{a} m_{b} m_{c}\right)}{\left(\varepsilon_{b}+\frac{\not h^{2} q_{b}^{\prime 2}}{2 \mu_{b}}\right)\left(\varepsilon_{a}+\frac{\not h^{2} q_{a}^{2}}{2 \mu_{a}}\right)} \tag{3.5}
\end{equation*}
$$

with

$$
\begin{equation*}
\mathrm{f}_{\alpha}\left(\overrightarrow{\mathrm{q}}_{\alpha} \mathrm{m}_{\beta}^{\mathrm{m}}\right)=\left\langle\overrightarrow{\mathrm{q}}_{\alpha} \mathrm{m}_{\beta} \mathrm{m}_{\gamma}\right| \mathrm{v}_{\alpha}\left|\psi_{\alpha}\right\rangle, \quad(\alpha \neq \beta \neq \gamma) \tag{3,6}
\end{equation*}
$$

The momenta $\vec{k}_{a}, \vec{k}_{c}, \vec{k}_{b}^{\prime}$ and $\vec{k}_{c}^{\prime}$ evaluated for $\vec{p}_{c}=\vec{p}_{c}^{\prime}$ have been dino ted by $\overrightarrow{\mathrm{q}}_{\mathrm{a}}, \overrightarrow{\mathrm{q}}_{\mathrm{c}}, \quad \overrightarrow{\mathrm{q}}_{\mathrm{b}}^{\prime} \mathrm{c}$ and $\overrightarrow{\mathrm{q}}_{\mathrm{c}}^{\prime}$ respectively. In eqs. (3.4) and (3.5) $\mu \alpha$ and $\nu_{\alpha}$ are the reduced masses for the $\beta-\gamma$ subsystem and for the system consisting of $\alpha$ and $\beta+\gamma$, respectively. The energy shifting $\mathrm{S}_{\mathrm{c}}$, coming from the prescription (3.4), is given by

$$
\begin{equation*}
S_{c}=E-\varepsilon_{a}-\frac{\not h^{2} p_{c}^{2}}{2 v_{c}}=\frac{\not h^{2} p_{b}^{\prime 2}}{2 v_{b}}-\varepsilon_{b}-\frac{\not h^{2} p_{c}^{2}}{2 v_{c}}, \tag{3.7}
\end{equation*}
$$

where $\varepsilon_{\alpha}$ is the binding energy of the bound state in the channel $\alpha$ and $E=\not h^{2} p_{a}^{2} / 2 \nu_{a}$ is the entrance channel energy in the total center of mass system.

The nucleon-nucleus form factors $f_{\alpha}\left(\overrightarrow{\mathrm{q}}_{\alpha} \mathrm{m}_{\beta} \mathrm{m}_{\gamma}\right)$ defined by eq. (3.6) may be written, by means of usual angular momentum expansions $(7,27)$, in the form

$$
\begin{align*}
& \mathrm{f}_{\alpha}\left(\overrightarrow{\mathrm{q}}_{\alpha} \mathrm{m}_{\beta} \mathrm{m}_{\gamma}\right)=-\left(\frac{2}{\pi}\right)^{\frac{1}{2}} \frac{\not 2^{2}}{2 \mu_{\alpha}} \sum_{\substack{j_{\alpha} 1_{\alpha} \\
\mathrm{m}_{\mathrm{j}_{\dot{\alpha}}} \mathrm{m}_{1_{\alpha}}}} \mathrm{N}_{1_{\alpha}} \beta_{\mathrm{j}_{\alpha} 1_{\alpha}}\left\langle\mathrm{j}_{\alpha} \mathrm{s}_{\gamma} \mathrm{m}_{\mathrm{j}_{\alpha}} \mathrm{m}_{\gamma} \mid \mathrm{s}_{\mathrm{N}} \mathrm{~m}_{\mathrm{N}}\right\rangle . \tag{3.8}
\end{align*}
$$

with

$$
\begin{equation*}
\mathrm{F}_{1_{\alpha}}\left(\mathrm{q}_{\alpha}\right)=\mathrm{i}^{-1} \alpha_{\mathrm{N}_{1}}^{-1}\left(\mathrm{q}_{\alpha}^{2}+\chi_{\alpha}^{2}\right) \int \mathrm{j}_{1_{\alpha}}\left(\mathrm{q}_{\alpha} \mathrm{r}\right) \mathrm{u}_{1_{\alpha}}(\mathrm{r}) \mathrm{r}^{2} \mathrm{dr} . \tag{3.9}
\end{equation*}
$$

In eqs. (3.8) and (3.9) the symbol $N$ stands for the nucleus $(\beta+\gamma)$, while the meaning of $s_{\alpha}$ and of the bound-state quantum numbers $j_{\alpha}$, $1_{\alpha}, \mathrm{m}_{\mathrm{j}_{\alpha}}, \mathrm{m}_{1_{\alpha}}$ is quite transparent; $\mathrm{u}_{1_{\alpha}}(\mathrm{r})$ is the radial part of the bound-state wave function $\psi_{\alpha}$ and $\mathrm{N}_{1 \alpha}$ its asymptotic normalization constant; $\chi_{\alpha}^{2}$ is expressed in terms of the binding energy $\varepsilon_{\alpha}$ by $\not h^{2} \chi_{\alpha}^{2}=2 \mu_{\alpha} \varepsilon_{\alpha}$. The constants $\beta_{j_{\alpha} 1_{\alpha}}$ and $N_{1 \alpha}$ are related to the spec troscopic factors and single-particle reduced widths, respectively, as conventionally used in direct nuclear reaction theories.

For the sake of completeness, let us give also the momentum--space representation of the amplitude (2.15). Adding to the amplitude (3.5) the polar contribution (2.13) one obtains after some kinematic variable transformations ${ }^{(22)}$ the following expression

where

$$
\psi_{c}^{(+)}\left(\vec{q}_{c}^{\prime} \vec{q}_{c} m_{a}^{\prime} m_{b}^{\prime} m_{a} m_{b} ; z\right)=\delta\left(\vec{q}_{c}^{\prime}-\vec{q}_{c}\right) \delta_{m_{a}^{\prime} m_{a}} \delta_{m_{b}^{\prime} m_{b}}+
$$

$$
\begin{equation*}
+\frac{\left\langle\vec{q}_{c}^{\prime} m_{a}^{\prime} m_{b}^{\prime}\right| \hat{t}_{c}(z)\left|\vec{q}_{c} m_{a} m_{b}\right\rangle}{z-\frac{\not h^{2} q_{c}^{2}}{2 \mu_{c}}} \tag{3.11}
\end{equation*}
$$

is the two-body scattering state $\left(1+\hat{t}_{c} \hat{G}_{o}\right)\left|\vec{q}_{c} m_{a} m_{b}\right\rangle$ for the $a-b$ sub system in the momentum-space representation. The polar amplitude does not involve two-body off-shell interactions and does not influence the behaviour of the transition amplitude in the forward angle region, as already mentioned in Sect. 2. For these reasons it will be ignored in our specific calculations.
12.

## 3. 2. - The Neutron-Proton off-Energy-Shell t-Matrix Elements.

To evaluate the amplitude ( 3.5 ) one needs the expression of the off-shell t-matrix elements. We start from the widely used assumption that the two -nucleon transition operator is dominated by the deuteron bound state and the singlet virtual state $(13,24,28-30)$. This assumption leads to the use of a nonlocal separable two-nucleon intraction

$$
\begin{equation*}
v_{c}\left(\overrightarrow{k^{\prime}}, \vec{k}\right)=-\frac{\not 2^{2}}{2 \mu_{c}} \sum_{n=0,1} f_{n}\left(\vec{k}^{\prime}\right) \lambda_{n^{\prime}} f_{n}(\vec{k}) P_{n}, \tag{3.12}
\end{equation*}
$$

where $P_{n}$ are projection operators onto the deuteron state ( $n=0$ ) and the singlet state ( $n=1$ ). In this approximation for the potential, the two-body LS equation for the t-matrix elements can be easily solved to give

$$
\begin{equation*}
t_{c}\left(\vec{k}^{\prime} ; \vec{k} ; z\right)=-\frac{\not n^{2}}{2 \mu_{c}} \sum_{n=0,1} f_{n}\left(\vec{k}^{\prime}\right) \dot{\tau}_{n}(\mathrm{z}) f_{\mathrm{n}}\left(\vec{k}^{\mathrm{k}}\right) \mathrm{P}_{\mathrm{n}}, \tag{3.13}
\end{equation*}
$$

where

$$
\begin{equation*}
\tau_{\mathrm{n}}^{-1}(\mathrm{z})=\lambda_{\mathrm{n}}^{-1}\left\{1+\frac{\not h^{2} \lambda_{\mathrm{n}}}{2 \mu_{\mathrm{c}}} \int \frac{\left|\mathrm{f}_{\mathrm{n}}(\overrightarrow{\mathrm{q}})\right|^{2}}{\mathrm{z}-\frac{\underline{h}^{2} q^{2}}{2 \mu_{\mathrm{c}}}} \mathrm{~d} \overrightarrow{\mathrm{q}}\right\} \tag{3.14}
\end{equation*}
$$

If the nucleon-nucleon form factors $\mathrm{f}_{\mathrm{n}}(\vec{k})$ are chosen, as usual ${ }^{(24,29,30)}$, to be of the Yamaguchi form ${ }^{(31)}$

$$
\begin{equation*}
\mathrm{f}_{\mathrm{n}}(\overrightarrow{\mathrm{k}})=1 /\left(\mathrm{k}^{2}+\beta_{\mathrm{n}}^{2}\right) \tag{3.15}
\end{equation*}
$$

one has

$$
\begin{equation*}
\tau_{\mathrm{n}}(\sigma+\mathrm{i} \gamma)=\lambda_{\mathrm{n}} \frac{\left[\beta_{\mathrm{n}}-\mathrm{i}(\sigma+\mathrm{i} \gamma)^{1 / 2}\right]^{2}}{\left[\beta_{\mathrm{n}}-\mathrm{i}(\sigma+\mathrm{i} \gamma)^{1 / 2}\right]^{2}-\zeta_{\mathrm{n}}^{2}} \tag{3.16}
\end{equation*}
$$

with $\sigma=2 \mu_{c} S_{c} / h^{2}, \zeta_{n}^{2}=\lambda_{n} \pi^{2} / \beta_{n}$ and the prescription

$$
-\mathrm{i}(\sigma+\mathrm{i} \gamma)^{1 / 2}= \begin{cases}-\mathrm{i}\left|\sigma^{1 / 2}\right|+\gamma & \text { for } \sigma>0  \tag{3.17}\\ \left|(-\sigma)^{1 / 2}\right|-\mathrm{i} \gamma & \text { for } \sigma<0\end{cases}
$$

The parameters $\lambda_{\mathrm{n}}$ and $\beta_{\mathrm{n}}$ are chosen with the prescription of fitting the deuteron binding energy, the triplet and singlet scattering lengths and the singlet effective range. Using the experimental data of ref. (32) for the triplet parameters and of ref. (29) for the singlet ones, one obtains for the np system ${ }^{(x)}$
(3.18a) $\quad \beta_{o}=1.440 \mathrm{fm}^{-1}, \quad \lambda_{\mathrm{o}}=0.407 \mathrm{fm}^{-3}$;
(3.18b)

$$
\beta_{1}=1.153 \mathrm{fm}^{-1}
$$

$$
\lambda_{1}=0.145 \mathrm{fm}^{-3}
$$

Since the quantities (3.13) act into total spin-space for the np system, the t-matrix element appearing in (3.5) reads as follows

$$
\left\langle\overrightarrow{\mathrm{q}}_{c}^{\prime} \mathrm{m}_{\mathrm{a}}^{\prime} \mathrm{m}_{b}^{\prime}\right| \hat{\mathrm{t}}_{\mathrm{c}}\left(\mathrm{~S}_{\mathrm{c}}+\mathrm{i} \gamma\right)\left|\overrightarrow{\mathrm{q}}_{c} m_{a} m_{b}\right\rangle=
$$

$$
\begin{equation*}
=-\frac{\not x^{2}}{2 \mu_{c}} \sum_{n=0,1} c_{n}\left(m_{a}^{\prime} m_{b}^{\prime} m_{a} m_{b}\right) f_{n}\left(\vec{q}_{c}^{\prime}\right) \tau_{n}(\sigma+i \gamma) f_{n}\left(\vec{q}_{c}\right) . \tag{3.19}
\end{equation*}
$$

The constants $c_{n}$ coming from vector-coupling procedures have the following form
(3.20a)

$$
\begin{aligned}
& c_{0}\left(m_{a}^{\prime} m_{b}^{\prime} m_{a} m_{b}\right)=\frac{1}{2}\left(1+\delta_{\left.m_{a}^{\prime} m_{b}^{\prime} \delta_{m_{a}} m_{b}\right) \delta_{m_{a}^{\prime}}^{\prime}+m_{b}^{\prime}, m_{a}+m_{b},}^{c_{1}\left(m_{a}^{\prime} m_{b}^{\prime} m_{a} m_{b}\right)=-\frac{1}{2}(-1)^{m_{a}^{\prime}+m_{a}} \delta_{m_{a}^{\prime},-m_{b}^{\prime} \delta_{m_{b}},-m_{a}} .} .\right.
\end{aligned}
$$

(x) - Since our three-body model involves a definite pair of nucleons (the incident proton and the emitted neutron, or viceversa) and the inert core c, we do not take an average over the $n p$ and $n n$ singlet da ta to determine the singlet parameters. The average values would be slightly different from the values (3.18b). Furthermore, notice that exchange terms arising from antisymmetric properties with respect to all the nucleons (included the core ones), cannot be taken into account in our three-body context. However, their effect on the shape of the angular distribution is expected to be small (see refs. (10) and (33)).

## 3. 3. - The t-Matrix Amplitudes and the Born Ones.

By inserting eqs. (3.8) and (3.19) in eq. (3.5), one gets an explicit expression for the knock-out triangular diagram amplitude. If the fundtion $\tau_{\mathrm{n}}(\sigma)$ is replaced by the constant $\lambda_{\mathrm{n}}$, one has from (3.5) the friangular amplitude in the Born approximation for the two -body $t_{c}$-matrix (see eqs. (3.13) and (3.12)). In this approximation the off-energy-shell effects due to $\tau_{n}(\underline{\sigma}+i \gamma)$ disappear, because there is no dependence on the two-body energy $S_{c}=\not h^{2} \sigma / 2 \mu_{c}$ for the abb subsystem. Putting

$$
\begin{equation*}
\alpha_{\mathrm{n}(\mathrm{~T})}=\tau_{\mathrm{n}}, \tag{3,21}
\end{equation*}
$$

$$
\alpha_{n(B)}=\lambda_{n},
$$

one can write
(3. 22)
where

$$
\begin{align*}
& m_{j_{a}} m_{1_{a}} m_{c} m_{b} \\
& m_{j_{b}} m_{l_{b}} m_{a}^{\prime} \\
& C_{j_{a} 1_{a}}  \tag{3.23}\\
& j_{b} l_{b}
\end{align*}=\left\langle j_{a} s_{c} m_{j_{a}} m_{c} \mid s_{A} m_{A}\right\rangle\left\langle 1_{a} s_{b} m_{1_{a}} m_{b} \mid j_{a} m_{j_{a}}\right\rangle
$$

$$
\cdot\left\langle j_{b} s_{c} m_{j_{b}} m_{c} \mid s_{B} m_{B}\right\rangle\left\langle I_{b} s_{a} m_{1_{b}} m_{a}^{\prime} \mid j_{b} m_{j_{b}}\right\rangle,
$$

and

$$
\begin{aligned}
& \mathrm{J}_{\mathrm{b}} \mathrm{I}_{\mathrm{b}}
\end{aligned}
$$

$$
\begin{equation*}
\underset{h_{n ; 1} 1_{b}^{1}}{m_{1_{1}} m_{1_{b}}}(\vec{p})=\frac{\mathrm{Y}_{1}^{m_{1_{b}}^{*}}\left(\hat{\mathrm{q}}_{b}^{\prime}\right) \mathrm{F}_{1_{b}}\left(q_{b}^{\prime}\right) \mathrm{Y}_{1_{a}}^{m_{1_{a}}}\left(\hat{q}_{a}\right) F_{1_{a}}\left(q_{a}\right)}{\left(q_{b}^{\prime 2}+\chi_{b}^{2}\right)\left(q_{c}^{\prime 2}+\beta_{n}^{2}\right)\left(q_{c}^{2}+\beta_{n}^{2}\right)\left(q_{a}^{2}+\chi_{a}^{2}\right)} \tag{3.25}
\end{equation*}
$$

with $\mathrm{X}=\mathrm{T}, \mathrm{B}$ and $\overrightarrow{\mathrm{p}}=\overrightarrow{\mathrm{p}}_{\mathrm{c}}$.
In the following the integrals (3.24) with $\mathrm{X}=\mathrm{T}$, involving off--energy-shell t-matrix contributions will be called simply t-matrix ampltudes, while the integrals (3.24) with $\mathrm{X}=\mathrm{B}$, referring to the Born approximation for the t-matrix will be called Born amplitudes. We shall write

## 3.4. - Regularization of the singular triplet integrals.

In order to make the above formulae suitable for numerical cal culations, we shall now perform a convenient regularization of the in tegrals $\mathrm{T}_{0 ; 1}^{\mathrm{m}_{1} \mathrm{I}_{\mathrm{a}}{ }^{\mathrm{m}} \mathrm{l}_{\mathrm{b}}}$. The integrand in (3.24) for $\mathrm{n}=0, \mathrm{X}=\mathrm{T}$ and $\mathrm{E}>\bar{\varepsilon}_{\mathrm{a}}$ has a singular point at $p=p_{o}+i \gamma$ with

$$
\begin{equation*}
p_{o}=+\left[\frac{2 \nu_{c}}{\not ⿴ 囗^{2}}\left(E-\varepsilon_{a}+\varepsilon_{o}\right)\right]^{\frac{1}{2}}, \tag{3.27}
\end{equation*}
$$

corresponding to the deuteron pole $\mathrm{z}=\varepsilon_{0}+\mathrm{i} \gamma$ for the $\mathrm{t}_{\mathrm{c}}$-matrix elements (3.13), (3.14) ${ }^{(\mathrm{x})}$. In equation (3.27)

$$
\varepsilon_{o}=\not h^{2}\left(\zeta_{o}-\beta_{o}\right)^{2} / 2 \mu_{c}
$$

is the binding energy of the deuteron. Obviously, the singlet pole does not lie on the integration path, being $\zeta_{1}-\beta_{1}<0$.

The integrals $T_{0 ; 1_{a} l_{b}}^{m_{1} m_{b}}$ could be calculated for several continuously decreasing values of the small positive parameter $\gamma$ and the results should be compared among themselves in order to reach a definite numerical accuracy. However this procedure is unpractical in numerical computation, as already discussed in refs. $(21,34)$. It is
(x) - Since we exclude too low incident energies (see Sect. 1), we shall perform calculations for $E>\varepsilon_{a}$.

FIG. 2 - Angular depend $\mathrm{e}_{\text {nce }}$ of the real and imaginary parts $R_{n}$, $I_{n}$ of the $t$-matrix ampli tudes and of the Born ones $\mathrm{B}_{\mathrm{n}}$ at 20 MeV . The upper part of the figure gives the triplet amplitudes ( $\mathrm{n}=0$ ) and the lower one gives the singlet amplitudes ( $\mathrm{n}=1$ ).

FIG. 3 - Angular dependence of the amplitudes $\overline{R_{n}, I_{n}}$ and $B_{n}$ at 100 MeV .

FIG. 4 - Comparison between the angular dependence of $\mathrm{S}_{\mathrm{T}}$ (full curve) and $\mathrm{S}_{\mathrm{B}}$ (dashed curve) for a) $\mathrm{E}=20 \mathrm{MeV}$ and b) $\mathrm{E}=100 \mathrm{MeV}$.
evaluated. In Figs. 6 and 7 we plot the t-matrix amplitudes and the Born ones for $1_{a}=1_{b}=0, R_{A} \simeq R_{B}=4 \mathrm{fm}$, in the forward scattering an gle region, for $\mathrm{E}=20$ and 100 MeV , respectively. Here also we have normalized the amplitudes to the value of the triplet Born one at $0^{\circ}$ and 100 MeV , denoting them by $R_{n}^{\prime}$, $I_{n}^{\prime}$ and $B_{n}^{\prime}$.

By analogy with the zero-range case, Figs. 8-10 give the angu lar dependence, for $\mathrm{E}=20$ and 100 MeV , and the energetic dependence, for $\theta=0^{\circ}$, of the quantities $S_{T}^{\prime}$ and $S_{B}$. They are proportional to the differential cross sections and are given by (4.8) and (4.9), respectively, with $\rho, R_{n}, I_{n}$ and $B_{n}$ replaced by $\rho^{\prime}, R_{n}^{\prime}, I_{n}^{\prime}$ and $B_{n}^{\prime}$. The normalization factor $\rho^{\prime}$ is defined as in the zero-range case.

Similar calculations carried out for $1_{a}=1_{b}=1$ give results close to the above ones. An example is shown in Fig. 11, where the amplitude $B_{n}^{\prime \prime}$ (i.e. $B_{n ; 11}^{00}$ normalized as in the above cases) is compared with the corresponding t-matrix amplitudes $R_{n}^{\prime \prime}$ and $I_{n}^{\prime \prime}$ for $E=20 \mathrm{MeV}$.

Calculations performed at 50 MeV give, as far as off-energy--shell effects are concerned, results intermediate between the 20 and 100 MeV ones. The behaviour of the transition amplitudes and of the cross sections in the backward angle region is not plotted in the figures, for the reasons explained in the preceding Sections.

The finite-range results confirm the importance of the off--energy-shell t-matrix contributions in the range of the incident energy usually explored in experiments. In fact, a certain discrepan cy between the t-matrix results and the Born ones remains even at 100 MeV .

In comparison with the zero-range results we observe that fini te-range effects cause an oscillatory behaviour and a stronger decrea se with angle of the differential cross section. Owing to the presence of the propagators (3.15) in (3.13), our t-matrix amplitude is more decreasing with angle than the triangular amplitude constructed with a constant four-ray vertex function. Such a strong decrease is needed in order to reproduce the experimental data ${ }^{(x)}$. The occurence of the deep minima in Figs. 8 and 9 is due to the absence, in our formalism, both of mechanisms different from the triangular one as well as of
(x) - For a detailed comparison with experiments one must remove the above simplifying mass restrictions and introduce the channel distorsions. Thus, rather cumbersome and high-dimensional integrals have to be evaluated. In this paper, we are mainly interested in the analysis of the off-energy-shell effects and, to perform this program, we resort to a calculational model which preserves the gross features of the actual transition amplitudes.

FIG. 6 - Angular dependence of the real and ima ginary parts $R_{n}^{1}, I_{n}^{1}$ of the $t$-matrix amplitudes and of the Born ones $\mathrm{B}_{\mathrm{n}}^{\prime}$ at 20 MeV . The upper part of the figure gives the triplet amplitudes (vertical right scale) and the lower one gives the singlet amplitudes (vertical left scale).

FIG. 7 - Angular dependence of the amplitudes $\mathrm{R}_{\mathrm{n}}^{1}, \mathrm{I}_{\mathrm{n}}^{1}$ and $\mathrm{B}_{\mathrm{n}}^{1}$ at 100 MeV .

FIG. 8 - Comparison between the angular dependence of $S_{T}^{\prime}$ and $S_{B}^{\prime}$ for $E=20 \mathrm{MeV}$.

FIG. 9 - Comparison between the angular dependence of $S_{T}^{\prime}$ and $S_{B}^{\prime}$ for $E=100 \mathrm{MeV}$.

FIG. 10 - Comparison between the energetic dependence of $\mathrm{S}_{\mathrm{T}}^{\prime}$ and $\mathrm{S}_{\mathrm{B}}^{\prime}$ at $\theta=0^{\circ}$.

FIG. 11 - Angular dependence of the amplitudes $R_{n}^{\prime \prime}$; $I_{n}^{\prime \prime}$ and $B_{n}^{\prime \prime}$ at 20 MeV .
channel distorsions (the latter ones correspond to a phenomenological simulation of the higher-order terms in the multiple-scattering series). The polar graph amplitude, which is, in the heavy-core approximation, a slowly increasing function of the angle, and the higher-order terms provide a roughly isotropic background contribution in the forward an gle region.

We notice, as a general feature of the results obtained for the amplitudes, the predominance of the triplet contributions over the singletones (see Figs. 2, 3, 6, 7 and 11). This fact justifies, a posteriori, the correctness of the separable potential approximation (3.12). Furthermore the triplet contributions are enhanced by the weight factors which appear in the formulae (4.8) and (4.9) and arise from the particular structure of the coefficients (3.20).

In conclusion, the most relevant difference between the t-matrix predictions and the Born ones appears in the absolute magnitude of the cross sections. The shape of the angular distribution is only roughly the same in both cases, while the energetic dependence seems to be rather different at lower energies.

The above results about the importance of the off-energy-shell effects in nucleon-exchange reactions agree with similar results obtai ned for different nuclear processes, as break-up $(9,11)$ and heavy-ion neutron tunnelling reactions ${ }^{(27)}$.

We are pleased to thank Professor C. Villi for his continuous interest and stimulating suggestions throughout this work. Thanks are also due to Prof. G. Pisent for discussions and to Mr. G. Salmasso for his assistance during the working out of the numerical computation.
