(ricevuto il 23 Febbraio 1961)

1. - Recent results on the elastic scattering of electrons show that the proton has a hard core in which part of its charge is concentrated. It seems reasonable to expect that this feature of the structure of the nucleons will manifest itself also in their weak interactions with high momentum transfer, in reactions of the kind:

$$(1) \quad \begin{cases} \bar{\nu} + p \rightarrow n + e^+, \\ \nu + n \rightarrow p + e^-. \end{cases}$$

These processes have been investigated in a precedent letter (1,2). Under the assumptions specified in I the differential cross sections for these processes were found (I, (7), (8)) to depend essentially on three form factors F_1 , F_2 , H_1 , functions of the momentum transfer k^2 . These were supposed to be connected to the electromagnetic form factors of the nucleon through the relations

$$(2) \quad F_1(k^2) = F_1^V(k^2),$$

$$(3) \quad F_2(k^2) = F_2^V(k^2),$$

$$(4) \quad H_1(k^2) = \frac{G_A}{G} F_1^V(k^2),$$

F_1^V and F_2^V are the form factors for the isotopic vector part of the charge and anomalous magnetic moment of the nucleon. While (2) and (3) are consequences of the hypothesis of conservation of the vector current in β -interaction, (4) is a reasonable guess.

BERNARDINI: *Proceedings of the 1960 Annual International Conference on High Energy Physics at Rochester*, p.581.

Experimental evidence at that time favored an exponential distribution for the density of both charge and magnetic moment of the nucleon, giving

$$(5) \quad F_1^V(k^2) \approx F_2^V(k^2) \approx \left(1 + \frac{k^2}{a^2}\right)^{-2}.$$

The total cross-section for processes (1) thus evaluated (see I) increases at low energy with the square of the c.m. energy, but levels off, at $\mathcal{E} \approx a$, to a limiting value $\sigma_\infty (\approx 0.75 \cdot 10^{-38} \text{ cm}^2$, if $a^2 \approx 37.5 \mu_\pi^2$).

The new data on the proton form factors ⁽³⁾ show that while the magnetic form factor falls to zero more rapidly than expected from eq. (5), the charge form factor levels off to a plateau value of ≈ 0.42 . On the basis of eq. (2)-(4) we expect a similar behaviour to be exhibited also by the form factors F_1, F_2, H_1 .

This will produce a substantial modification of the quantitative results of I. In fact in the processes we are considering the decrease of the differential cross-section with increasing momentum transfer is only due to the decrease of the form factors of the nucleon. In the case of the scattering of electrons, on the contrary, high momentum transfers are already depressed by the propagator of a virtual photon, which introduces a factor $(k^2)^{-2}$ in the cross section.

2. - The differential cross section in the laboratory system for production of e^\pm through processes (1) is given by (I, (7), (8)). If one uses (2)-(4), it can be written:

$$(6) \quad \frac{d\sigma^\pm}{d \cos \theta} = \frac{G^2 \mathcal{E}^2}{\pi} \left(1 + \frac{2\mathcal{E}}{M} \sin^2 \frac{\theta}{2}\right)^3 \left\{ \cos^2 \frac{\theta}{2} (F_1^V(k^2))^2 + \right. \\ \left. + \frac{k^2}{4M^2} \left[2(F_1^V(k^2) + \mu F_2^V(k^2))^2 \operatorname{tg}^2 \frac{\theta}{2} + \mu^2 (F_2^V(k^2))^2 \right] \right\} + \\ + \left(\frac{G_A}{G} F_1^V(k^2) \right)^2 \left[1 + \sin^2 \frac{\theta}{2} + 2 \frac{\mathcal{E}^2}{M^2} \frac{\sin^4 \theta/2}{1 + 2(\mathcal{E}/M) \sin^2 \theta/2} \right] + \\ \mp \frac{G_A}{G} F_1^V(k^2) (F_1^V(k^2) + \mu F_2^V(k^2)) \frac{4 \sin^2 \theta/2}{1 + 2(\mathcal{E}/M) \sin^2 \theta/2} \left(\frac{\mathcal{E}}{M} + \frac{\mathcal{E}^2}{M^2} \sin^2 \frac{\theta}{2} \right) \right\}.$$

Where \mathcal{E} is the neutrino energy, θ the angle of emission of the electron, M the nucleon mass. We have tabulated this expression for different neutrino energies as a function of $\cos \theta$, making use of two different sets of values for the form factors F^V ⁽⁴⁾:

- 1) Set α : eq. (5) was used with $a^2 = 37.5 \mu_\pi^2$:
- 2) Set β : the F^V were assumed to coincide with the form factors of the proton as given in ⁽³⁾; for high momentum transfer F_1^V was assumed to remain at a constant value.

⁽³⁾ R. HOFSTADTER, F. BUMILLER and M. CROISSIAUX; *Phys. Rev. Lett.*, 5, 263 (1960).

⁽⁴⁾ For both sets, $G_A/G = 1.21$; $\mu = 3.7$.

In Fig. 1 we show the differential cross-section at $\mathcal{E}=1.84M$. Set β has a substantial tail at large angles. Table I gives the total cross-section at various energies; set β gives higher cross-section, which increase linearly with the energy \mathcal{E} .

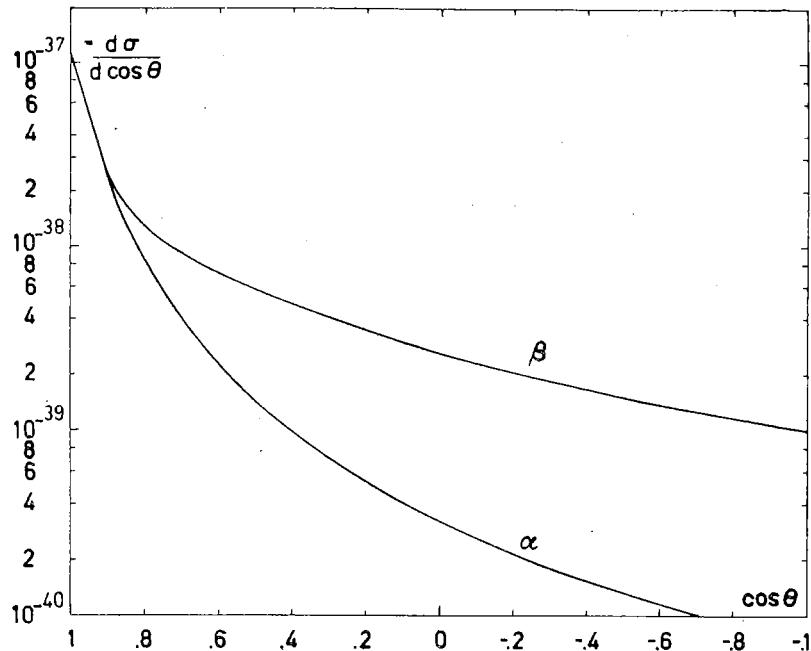

Fig. 1. - Differential cross-section in the laboratory system for the process $\nu + n \rightarrow p + e^-$ at a neutrino energy $\mathcal{E}=1.84 M$.

TABLE I. - Total cross-section for processes (1) at different neutrino energies, in cm^2 .

\mathcal{E}/M	Set α		Set β	
	$\sigma_v \cdot 10^{38}$	$\sigma_{\bar{v}} \cdot 10^{38}$	$\sigma_v \cdot 10^{38}$	$\sigma_{\bar{v}} \cdot 10^{38}$
0.43	0.60	0.15	0.60	0.15
0.62	0.75	0.22	0.75	0.22
0.89	0.925	0.29	0.865	0.31
1.28	0.845	0.38	1.024	0.44
1.84	0.832	0.46	1.31	0.60
2.66	0.81	0.53	1.68	0.81
3.83	0.79	0.56	2.48	0.97
5.52	0.76	0.59	3.69	1.72

We must remark that set β implies an extrapolation of the present knowledge of the nucleon structure to regions of higher momentum transfers, which is perhaps unrealistic, being equivalent to the assumption of a pointlike nucleon core. A bigger uncertainty is due to the ignorance of the neutron form factor. These results, however, stress the fact that the behaviour of the cross-section for processes (1) is strongly dependent on the nucleon form factors for high momentum transfer, and that conversely from these processes we can gain information on features of the nucleon, such as the radius of its core, which are as yet unknown.
