## ABSTRACT

Previous calculations of  $o(\alpha_s^3)$  corrections to inclusive jet production in hadron collisions are extended to finite size jet cones and successfully compared with UA2 and CDF experimental data.

---

A precise determination of inclusive jet cross-section in hadronic collision at high energies is very important in order to provide decisive tests of parton - parton dynamics within the standard model and eventual evidence of new physics. Recent calculations<sup>[1][2]</sup> of  $o(\alpha_s^3)$  corrections have been performed for jet cross-sections, which start to be properly defined from that order of perturbation theory, and show a reduced theoretical sensitivity to the renormalization and factorization scales , as compared to the Born  $o(\alpha_s^2)$  terms. Those results have been obtained either for all subprocesses in a fully analytical form limited to small jet cone sizes  $\delta \ll 1$ <sup>[1]</sup>, or for the pure glue case for finite size cones up to  $\frac{\pi}{3}$ <sup>[2]</sup>. On the experimental side UA2<sup>[3]</sup> and CDF<sup>[4]</sup> collaborations have given results up to jet transverse momentum  $p_t \approx 200 \text{ GeV}/c$ , with various jet algorithms and kinematical cuts.

The aim of the present letter is to extend the analysis of ref.<sup>[1]</sup> to a more general configuration which takes into account both the experimental definition of the jet algorithm and finite size effects. Our findings are then compared to the experimental data<sup>[3][4]</sup>.

We briefly discuss the method used. We start from the analytical results of ref.<sup>[1]</sup>, corresponding to the Furman<sup>[5]</sup> definition of the jet cone of semi-aperture angle  $\delta$ , for  $\delta \ll 1$ , obtained from the basic results of Ellis and Sexton<sup>[6]</sup> of virtual and real parton-parton subprocesses in n-dimensions. Then we add a further contribution, which is free of infrared and collinear singularities, and therefore can be calculated for  $n=4$ , which takes care of the finite cone size and the jet algorithm.

We first consider the case, à la Furman<sup>[5]</sup>, where the jet momentum  $P_J$  is well defined and it comes from the vectorial sum of hadrons momenta contained within a cone of size  $\Delta$ , with no restrictions on  $\Delta$ . This situation is realised in the UA2 jet algorithm<sup>[3]</sup>. Then the corresponding jet cross section  $d\sigma(\Delta)$  can be schematically written as

$$\frac{E_J d\sigma(\Delta)}{d^3 P_J} = \frac{E_J d\sigma_{an}(\delta)}{d^3 P_J} + \frac{E_J d\sigma_{num}(\Delta - \delta)}{d^3 P_J} \quad (1)$$

where  $d\sigma_{an}(\delta)$  is the analytical contribution already given in ref.<sup>[1]</sup> for small  $\delta$ , and  $d\sigma_{num}(\Delta - \delta)$  is the complementary contribution computed by performing the

TABLE 1 :

Inclusive jet cross section  $p_t^4 E \frac{d\sigma}{ds} p$  (nb GeV $^{-2}$ ) versus the cone size  $\Delta$  resulting from the analytical calculation (ANALYT.), the combined analytical and numerical one (NUMERIC.) and the Born term (one loop) only (BORN), for  $\sqrt{s} = 1.8$  TeV,  $\mu = P_t$ ,  $\theta = 90^\circ$  and various  $x_t = \frac{2p_t}{\sqrt{s}}$ .

numerical integration of the matrix elements squared. More precisely one obtains ( $p_{1,2}$  are two generic final partons)

$$\begin{aligned} d\sigma_{num}(\Delta - \delta) &\equiv d\sigma(p_1, p_2 \in C_{\Delta-\delta}; \overline{p_1} + \overline{p_2} = \overline{P_J}) + \\ &d\sigma(p_1 \in C_\delta, p_2 \in C_{\Delta-\delta}; \overline{p_1} + \overline{p_2} = \overline{P_J}) - \\ &d\sigma(p_1 \in C_\delta, p_2 \in C_{\Delta-\delta}; \overline{p_1} = \overline{P_J}) + \text{permutations}, \end{aligned}$$

where  $C_\delta$  and  $C_{\Delta-\delta}$  are the cone of semi-aperture  $\delta$  and the crown between the cones  $C_\delta$  and  $C_\Delta$ , respectively.

The numerical computation is performed by integrating over four variables using VEGAS. A more detailed discussion on the integration procedure will be given elsewhere[7].

In Table 1 we show the dependence of the resulting  $o(\alpha_s^3) + o(\alpha_s^2)$  cross section on the cone size  $\Delta$  for the subprocesses  $gg \rightarrow jet + X$  and  $q:\bar{q} \rightarrow jet + X$ , as compared to the analytical cross results of ref.[1], valid in principle for  $\delta \ll 1$ . Both the analytical and numerical predictions are precise up to  $o(2\%)$ . The validity of the analytical approximation up to  $\delta \leq 0.7 - 0.8$  is striking. This might be understood by observing that the neglected terms in the calculation are of order  $(\delta^2/4)$ , since they all come from the expansion of  $(1 - \cos \delta)/(1 + \cos \delta)$ .

We compare now our results with the UA2 data[3], which correspond to a value  $\Delta = \arccos(0.2) = 1.37$ . We have used two different sets of structure functions to have an idea of the theoretical uncertainty. The first choice, hereafter denoted by ACGG1, corresponds to the Diemoz et al.[8] parametrisation, with  $\Lambda = 160 MeV$  and  $m_t = 60 GeV$ , modified in order to be consistent with our factorization scheme, which absorbs the kinematical terms becoming large near the boundary of the phase space into the finite next-to-leading corrections to the structure functions. In ref.[1] this corresponds to the choice  $CQ=1$ . The second set corresponds to the Martin et al.[9] parametrisation, denoted by MRS2, characterised by a hard glue with  $\Lambda = 250 MeV$  and the  $\overline{MS}$  factorisation scheme. Both sets of structure functions include next-to-leading terms in the evolution programmes and reflect two extreme

descriptions of the glue distribution. As discussed in ref.[1] the scale dependence induce an uncertainty which ranges between  $\approx 10\%$  at  $x_t \approx 0.1$  and  $\approx 30\%$  at  $x_t \approx 0.6$ . Needless to recall that the Born terms only, with  $\alpha_s(\mu^2)$  to one loop, lead to an ambiguity of order of two.

Our results are shown in Fig.1, for  $\mu^2 = M^2 = p_t^2$  and compared with the UA2 data<sup>[3]</sup>. The parametrisation ACGG1 clearly describes the data better. However, the systematic uncertainty cannot rule out the MRS2 set. The mass scale uncertainty, reported above, is not shown in the figure. The agreement is excellent.

We discuss now the comparison with CDF data<sup>[4]</sup>. The correspondig jet algorithm leads to define a jet as a deposition of transverse energy  $E_t$  inside a circle  $C_R$  of radius  $R \equiv \sqrt{(\Delta\eta^2 + \Delta\Phi^2)} = 0.6$  in the rapidity - azimuthal angle plane, irrespective of the jet direction inside  $C_R$ . Furthermore the jet direction is varied in the range  $0.1 < |\eta| < 0.7$ . To approximate this experimental configuration we have considered within our analytical jet algorithm a cone of average value  $\delta \approx 0.55$ , and let its direction vary within the appropriate  $\eta$  range. This procedure is expected to be a rather good approximation of the CDF measurement, because of the weak (logarithmic) dependence on  $\delta$ , up to  $\delta \approx 0.8$ , as well as the reliability of the analytical results, as discussed above. It is clear that a more precise - but much longer - computation might be in principle achieved combining the analytical and numerical methods, appropriately modified to exactly match th CDF jet algorithm. We believe however that the improvement in the precision possibly gained so, would be smaller than the theoretical ambiguity coming from the scale dependence and the choice of the structure functions.

Our results are shown in Fig.2, using the ACGG1 structure functions and with  $\frac{3}{4}p_t \leq \mu = M \leq 2p_t$ . The agreement is clearly quite satisfactory. Notice the strong reduction of theoretical sensitivity to the mass scales from  $o(\alpha_s^2)$  to  $o(\alpha_s^3)$ . As discussed previously, in connection to the UA2 data, the choice of the structure functions induces a further ambiguity, not explicitly reported in Fig.2.

During the completion of this work we have been aware of a paper of S.D.

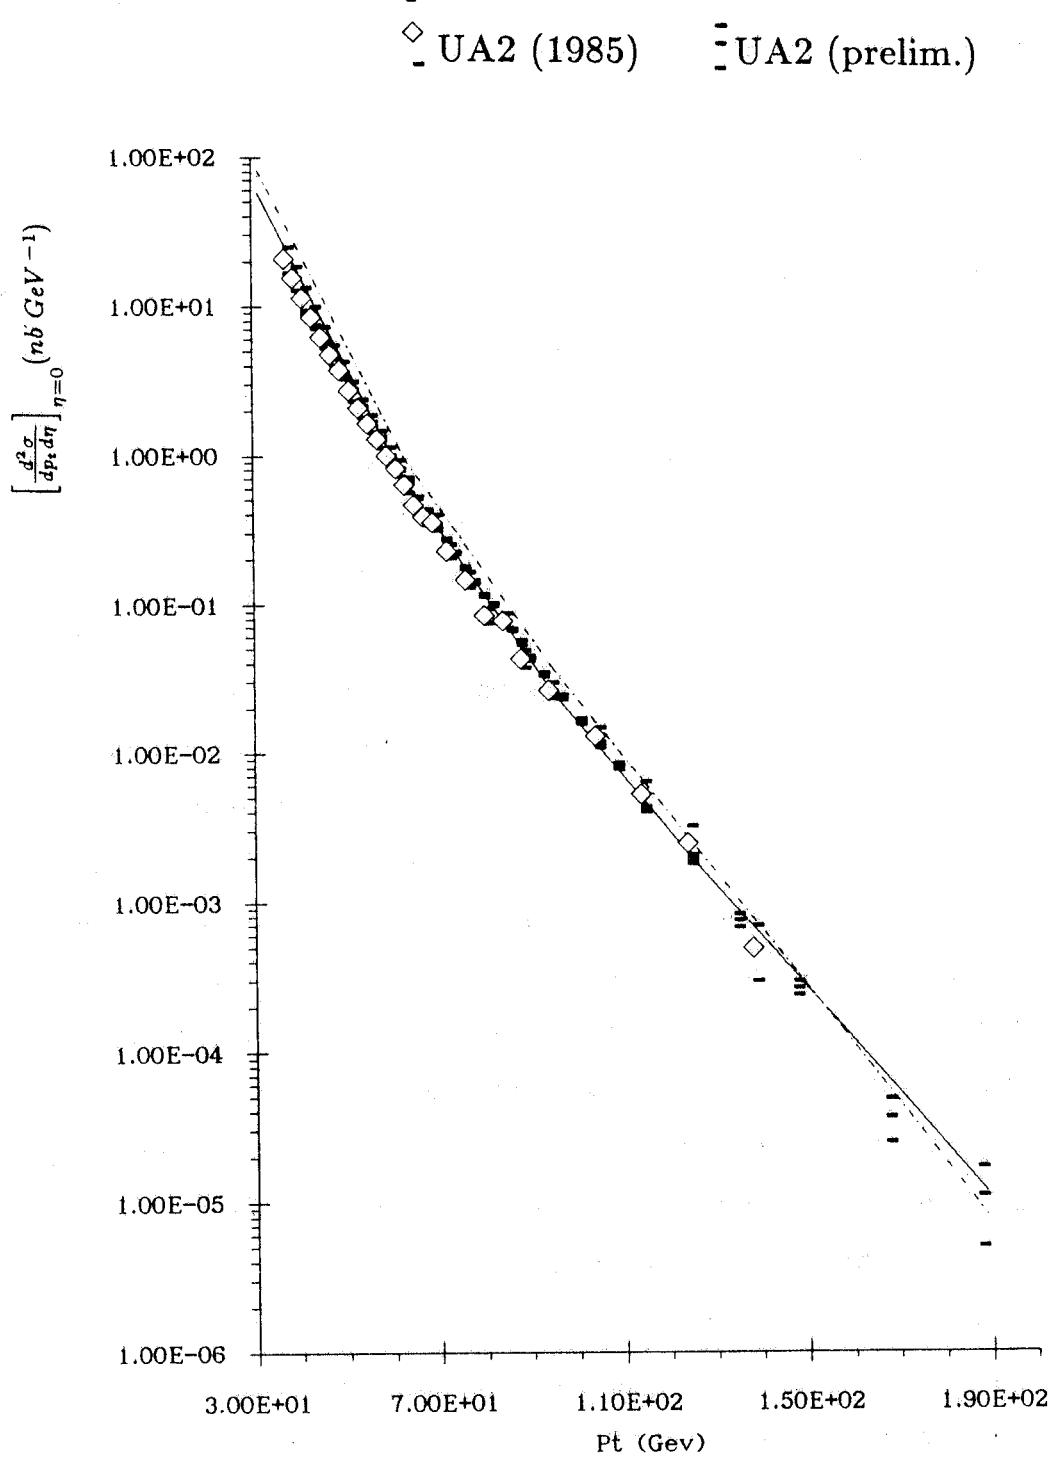

Fig.(1) :

Inclusive jet cross section  $\left[ \frac{d^2\sigma}{dp_t d\eta} \right]_{\eta=0} (\text{nb GeV}^{-1})$  versus  $p_t$ , for  $\sqrt{s} = 630 \text{ GeV}$ ,  $\mu = p_t$ , using the parametrisations of the structure functions ACGG1 (full line) and MRS (dotted). The data are from UA2 collaboration<sup>[3]</sup>. Statistical errors only are shown.

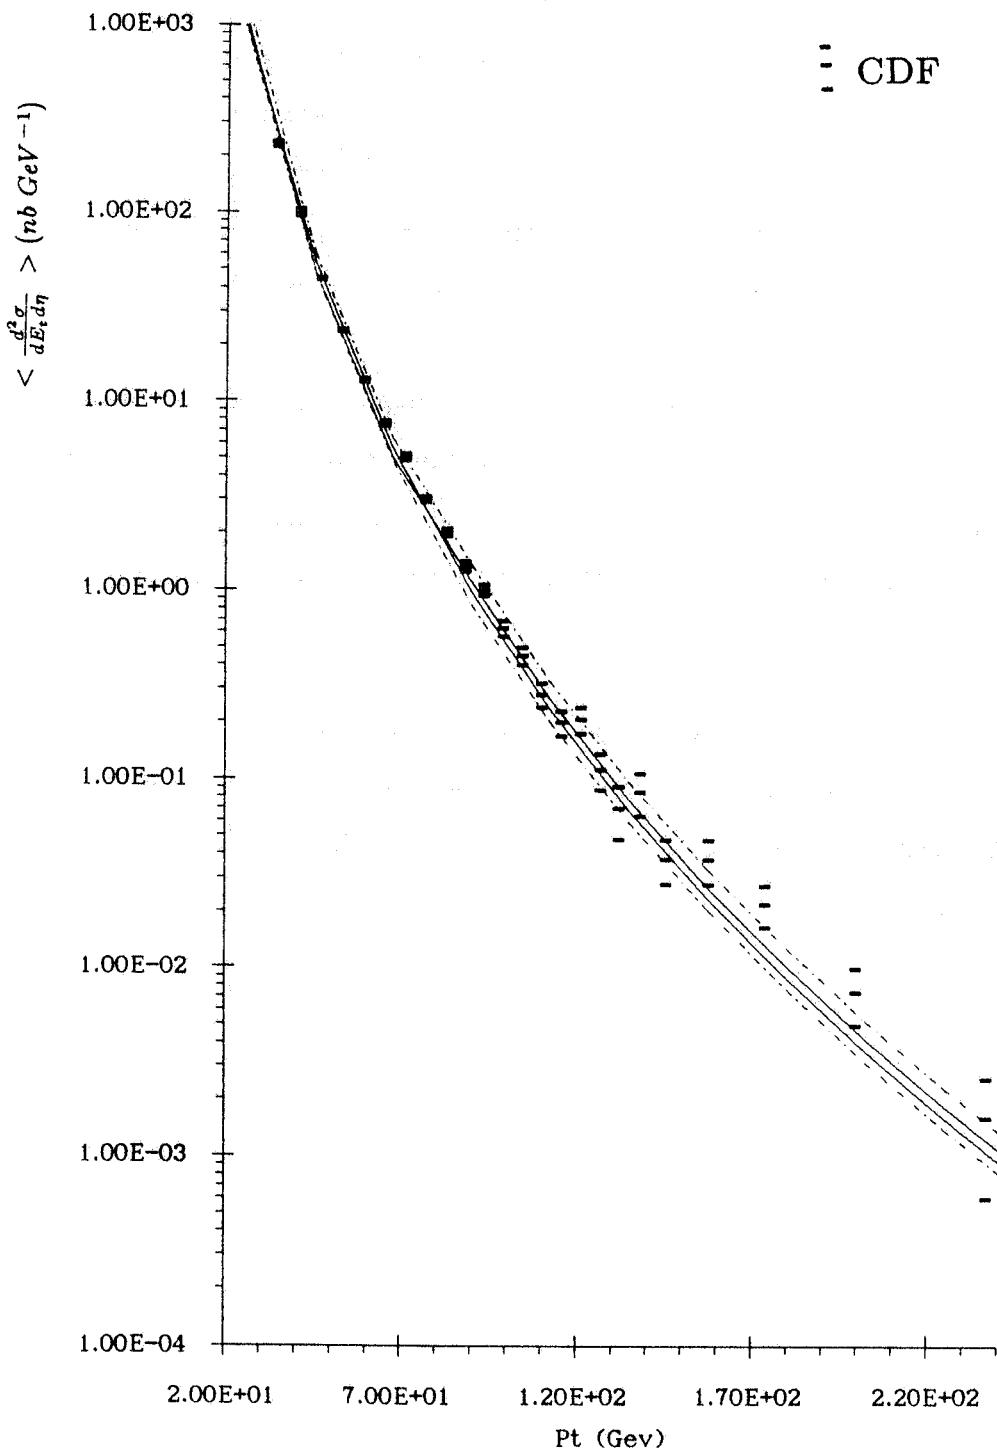

Fig.(2) :

Inclusive jet cross section  $\langle \frac{d^2\sigma}{dE_t d\eta} \rangle$  (nb GeV $^{-1}$ ) versus  $E_t$  at  $\sqrt{s} = 1.8$  TeV, for  $R = 0.6$  averaged over  $0.1 < |\eta| < 0.7$ , for  $\mu = 3/4 p_t$  (upper curve) and  $\mu = 2 p_t$  (lower curve). The dotted band refers to the Born (one loop) prediction. The data are from CDF collaboration<sup>[4]</sup>. Statistical errors only are shown.

Ellis, Z. Kunszt and D.E. Soper<sup>[10]</sup>, where a similar conclusion is reached on the basis of their jet algorithm much closer to CDF definition. On the other hand our approach is more directly applicable to the UA2 configuration which cannot be analysed in their case because of limitation  $R = \sqrt{(\Delta\eta^2 + \Delta\Phi^2)} < \frac{\pi}{3}$ . The two approaches have been found in excellent agreement to  $o(few\%)$  in some particular configurations (gluon - gluon scattering,  $\delta \ll 1$ ) where we could directly compare our results.

To conclude we have shown that  $o(\alpha_s^3)$  corrections improve sizably the QCD predicting power introducing the right dependence on the detector size, which is missing at the Born level, in agreement with data, and reduce the theoretical uncertainty to a level of  $o(30\%)$  which is comparable with the actual experimental accuracy.

We are grateful to M. Mangano, G. Marchesini and T. Sjostrand for discussions. We also thank L. Di Lella, P. Jenni and K. Meier for allowing us to use the UA2 preliminary data, and S. Bertolucci and A. Sansoni for discussions on the CDF jet algorithm.
