E. Recami and G. Ziino(x): EXPLAINING $\Delta I = \frac{1}{2}$ RULE AND THE EXISTENCE OF $K_{OS}$, $K_{OL}$: A NEW FOUR-QUARK SCHEME.

ABSTRACT:

A new four-quark scheme is suggested, in which the strange and charm quarks $\lambda, c$ are considered as the members of the $1/2$ representation (with $I = 0$) of a new "strange isospin" $S$. The new scheme is shown to be already contained in SU(4), and allows a different internal classification of hadron supermultiplets. Moreover, from the conservation law of the total isospin $T = \frac{1}{2} + \frac{3}{2}$, we succeed in particular in explaining: (i) the $\Delta I = 1/2$ rule for strangeness violating weak interactions; (ii) the existence of $K_{OS}$, $K_{OL}$.

1. - Let us observe that all the good features of the four-quark model(1-3) can be more straightforwardly derived from considering the third and fourth(4) quarks $\lambda, c$ as the members of the $1/2$ representation of a new "strange isospin" $S$.

In fact, let us consider the four quarks (with their electric charge) as in the charm model(1, 2):

(x) - Istituto di Fisica dell'Università di Palermo. Partially supported by CNR, under the contract no. 75/00442.02, c/o Istituto di Fisica Teorica dell'Università di Catania.
\[ \begin{align*} 
\{ n( q = -1/3) ; & \frac{\lambda( q = -1/3)}{ \lambda( q = -1/3)} ; \\
\{ p( q = + 2/3) ; & \frac{c( q = + 2/3)}{c( q = + 2/3)} . 
\end{align*} \]

where of course \( n, p, \lambda \) constitute the fundamental representation of \( SU(3) \).

As well-known, the quarks \( n, p \) are the members of the ordinary isospin \( I \), with strangeness \( S = 0 \) and charm \( C = 0 \):

\[ \begin{align*} 
n( I_3 = -1/2) ; & \frac{p( I_3 = + 1/2)}{p( I_3 = + 1/2)} . 
\end{align*} \]

Analogously, we can well consider the quarks \( \lambda, c \) as the members of the 1/2 representation (with \( I = 0 \)) of a new isospin \( S \), that we shall call "strange isospin" (or "strange spin"):

\[ \begin{align*} 
\frac{\lambda( S_3 = -1/2)}{\lambda( S_3 = -1/2)} ; & \frac{c( S_3 = + 1/2)}{c( S_3 = + 1/2)} . 
\end{align*} \]

In this way, as the "strange isospin" doublet \( \lambda, c \) is an ordinary-isospin singlet, so it is natural to consider the ordinary-isospin doublet \( n, p \) as a strange-isospin singlet.

Of course, in the present scheme the two quantum numbers strangeness, \( S \), and charm, \( C \), are very simply substituted in the case of our four quarks by the degrees of freedom \( S_3 = -1/2 \) and \( S_3 = +1/2 \), respectively, of the strange-isospin \( S \):

\[ \begin{align*} 
2S_3 = & \begin{cases} 
-1 = S(\lambda) ; \\
+1 = C(c) , 
\end{cases} 
\end{align*} \]

or better:

\[ \begin{align*} 
\frac{S(\lambda)}{2} = & \frac{S_3(\lambda)}{2} = -\frac{1}{2} ; \\
\frac{C(c)}{2} = & \frac{S_3(c)}{2} = +\frac{1}{2} . 
\end{align*} \]

The generalized Gell-Mann and Nishijima formula of the charm model:

\[ Q = I_3 + \frac{S+C}{2} + \frac{B}{2} , \]

in our scheme reads in the equivalent form:
We immediately want to forward three important consequences of our present, symmetric scheme.

Firstly, our quark model yields a straightforward explanation of the rule

\[ \Delta I = \frac{1}{2}, \]

for the (strangeness violating) weak interactions, as a consequence of the conservation of the vector \( I + \bar{S} \), that we shall call "total isospin" \( T \):

\[ \bar{T} = I + \bar{S}. \]

In other words, if we postulate the "total isospin" conservation law to hold for both all weak and the strong interactions, then we get immediately the \( \Delta I = 1/2 \) rule for all \( \Delta S = 1 \) weak interactions (or better for all \( \Delta \bar{S} = 1/2 \) weak interactions).

Secondly, let us consider the \( K_{0} \) and \( \bar{K}_{0} \) meson states, according to our (more symmetric) scheme:

\[
\begin{align*}
| K_{0} > & \sim | n > | \bar{S} = \frac{1}{2}; \quad I = \frac{1}{2}; \quad \bar{S}_{3} = \frac{1}{2}; \quad I_{3} = - \frac{1}{2} >; \\
| \bar{K}_{0} > & \sim | n > | \bar{S} = \frac{1}{2}; \quad I = \frac{1}{2}; \quad \bar{S}_{3} = - \frac{1}{2}; \quad I_{3} = + \frac{1}{2} >.
\end{align*}
\]

From the above definition (7), we get:

\[
\begin{align*}
| K_{0} > & = \frac{1}{\sqrt{2}} \left| T = 1; \quad T_{3} = 0 > + \frac{1}{\sqrt{2}} \left| T = 0; \quad T_{3} = 0 >; \quad (8a) \right.
| \bar{K}_{0} > & = \frac{1}{\sqrt{2}} \left| T = 1; \quad T_{3} = 0 > - \frac{1}{\sqrt{2}} \left| T = 0; \quad T_{3} = 0 >, \quad (8b) \right.
\end{align*}
\]

where of course it must be:

\[
\begin{align*}
| K_{0S} > & = | T = 1; \quad T_{3} = 0 >; \\
| K_{0L} > & = | T = 0; \quad T_{3} = 0 >. \quad (9)
\end{align*}
\]
4.

Since, in our assumptions, the total isospin \( T \) is conserved in weak interactions, it follows immediately that only the eigenstates, \( |K_{\infty}\rangle \), \( |K_{\pi L}\rangle \), of \( T \), \( T_3 \) can be actually "seen" through weak interactions.

Thirdly, still from conservation of \( T \), one can directly derive the CVC-hypothesis, in the case of \( \Delta S = 0 \) currents. Besides, even in the case of \( \Delta S \neq 0 \) isocurrents, one can define a generalized current (carrying \( T \)) and then derive the conservation of the generalized vector isocurrent, thus extending the original CVC-hypothesis to the total-isospin case.

3. Let us now come to the question of the algebraic structure underlying our four-quark model. Following Avilez-Valdez(7), from our required symmetries \( SU(2)_I, SU(2)_S, SU(3) \) we are automatically led to the sympletic group \( Sp(4) \) in four dimensions(8), which however is contained(8) in \( SU(4) : Sp(4) \subset SU(4) \). Therefore we stress that the usual charm model(1,2) itself must in particular include \( SU(2)_S \) as well as \( SU(2)_I \).

If we adopt \( SU(4) \) symmetry, then by our scheme we shall merely forward a different internal classification of supermultiplets.

For instance, the spin 1/2 baryon 20-plet of \( SU(4) \) becomes:

\[
\begin{align*}
\bar{S} & = 0; & I = \frac{1}{2}; & I_3 = \pm \frac{1}{2} & \rightarrow & npp \equiv P^+ \equiv P \\
I_3 & = -\frac{1}{2} & \rightarrow & npp \equiv N^0 \equiv N \\
\bar{S} & = \frac{1}{2}; & \bar{S}_3 = \pm \frac{1}{2}; & I = 0 & \rightarrow & c\lambda n \equiv N^0(c\lambda) \\
I_3 & = +1 & \rightarrow & c\gamma \lambda \equiv C^+(c\lambda) \\
I_3 & = 0 & \rightarrow & c\gamma n \equiv C^+(c\lambda) \\
I_3 & = -1 & \rightarrow & c\gamma n \equiv C^+(c\lambda) \\
\bar{S}_3 & = -\frac{1}{2}; & I = 0 & \rightarrow & c\lambda \lambda \equiv A^0(\lambda c) \\
I_3 & = +1 & \rightarrow & \lambda p n \equiv A^0 \equiv A \\
I_3 & = 0 & \rightarrow & \lambda p n \equiv \Sigma^0 \\
I_3 & = -1 & \rightarrow & \lambda n n \equiv \Sigma^-
\end{align*}
\]
\[
\begin{align*}
S &= 1; \quad \bar{S}_3 = +1; \quad I = \frac{1}{2}; \quad I_3 = +\frac{1}{2} \quad \longrightarrow \quad \text{ccp} \equiv \Sigma^{++}(cc) \\
I_3 &= -\frac{1}{2} \quad \longrightarrow \quad \text{ccn} \equiv \Sigma^{+}(cc) \\
\bar{S}_3 &= 0; \quad I_3 = +\frac{1}{2} \quad \longrightarrow \quad c\lambda p \equiv \Sigma^{+}(c) \\
I_3 &= -\frac{1}{2} \quad \longrightarrow \quad c\lambda n \equiv \Sigma^{0}(c) \\
\bar{S}_3 &= -1; \quad I_3 = +\frac{1}{2} \quad \longrightarrow \quad \lambda \bar{\lambda} p \equiv \Sigma^{0} \\
I_3 &= -\frac{1}{2} \quad \longrightarrow \quad \lambda \bar{\lambda} n \equiv \Sigma^{-}
\end{align*}
\]

where \(N^0 \equiv N\) is the neutron, \(P^+ \equiv P\) the proton, \(\Lambda^0 \equiv \Lambda\) the Lambda-baryon and \(C^+ \equiv C\) the newly discovered "charmed proton"\(^{(9)}\). The baryon names are preceded by their empirical "chemical formula" in terms of quarks.

It is noticeable e.g. the large mass-splitting in the \(\bar{S}_3 = \frac{3}{2}\) doublet of baryons \(\Lambda^0, C^+\); but it can be due to the so-called medium-strong interactions, which in fact are known to be invariant not under group SU(3), but only under the group SU(2) generated by ordinary isospin. More generally, the mass-splitting due to medium-strong interactions is expected to depend on both \(S\) and \(\bar{S}_3\), so that the "medium-strong" Hamiltonian is not expected to be invariant under the group SU(2) generated by \(S\).

Since we assumed strong interactions to be invariant also under SU(2)\(_S\), then the SU(3) symmetry among \(n, p, \lambda\) becomes - by a mere SU(2)\(_S\)-rotation - the SU(3) among \(n, p, c\). Therefore, by applying the Gell-Mann and Okubo formula to the alternative SU(3)-fundamental-representation \(n, p, c\), besides the usual mass relation\(^{(10)}\)

\[
\frac{3}{4}A + \frac{1}{4}\Sigma = \frac{1}{2}N + \frac{1}{2}\Sigma
\]

we can symmetrically write at the first order:

\[
\frac{3}{4}C^+ + \frac{1}{4}\Sigma(c) = \frac{1}{2}N + \frac{1}{2}\Sigma(c) , \tag{10}
\]

where \(\Sigma(c)\) is the mass of the triplet \(\Sigma^0(c), \Sigma^+(c), \Sigma^{++}(c)\), and \(\Sigma(c)\) of the doublet \(\Sigma^+(cc), \Sigma^{++}(cc)\). From the last two relations, one may also get:

\[
\frac{3}{4}C^+ + \frac{1}{4}\Sigma(c) - \frac{1}{2}\Sigma(c) = \frac{3}{4}A^0 + \frac{1}{4}\Sigma - \frac{1}{2}\Sigma . \tag{10'}
\]
The previous considerations will be derived elsewhere also from more general interaction-symmetry considerations\(^{(11)}\).

The authors are grateful to professors E. Bellotti, P. Castorina, C. Cronström, S. Ferrara, R. Mignani, M. Noga for useful discussions, and to prof. C. Avílez-Valdez for calling their attention to his unpublished report ref. (7). One of them (G. Z.) thanks profs. U. Palma and L. Scarsi for the kind interest.
