Istituto Nazionale di Fisica Nucleare - Sottosezione di Trieste
1. - INTRODUCTION

This paper reports the preliminary results of an experiment, which is now in progress, concerning the determination of the ratio between the cross-section of the \((n,n'\gamma)\) reaction and the cross-section of the \((n,p)\) reaction for \(14\ \text{MeV}\) neutrons and nuclei of light and medium atomic weight, for which the \((n,p)\) reaction is followed by a beta decay leading to an excited state of the original nucleus.

The preliminary measurements have been performed with a sample of siliconium and particular attention has been given to the de-excitation gamma ray of 1778.9 keV emitted in the transition of the \(\text{Si}^{28}\) nucleus from the first excited state to the ground state \((^1)\). The gamma rays were detected by means of NaI(Tl) crystals.

2. - DETERMINATION OF THE RATIO \(\sigma(n,n'\gamma)/\sigma(n,p)\)

When a nucleus \(z\,^{A}\,^{z}X\) is exposed to a beam of \(14\ \text{MeV}\) neutrons, it can participate either to the inelastic scattering reaction

\[
(1) \quad z\,^{A}\,^{z}X + n \rightarrow n' + \left[ z\,^{A}\,^{z}X \right]^* ,
\]

where the original nucleus is normally left in an excited state from which it decays with the emission of gamma radiation, or to the \((n,p)\) reaction

\[
(2) \quad z\,^{A}\,^{z}X + n \rightarrow p + z-1\,^{A}\,^{z}Y ,
\]

where the final nucleus can be beta -emitter, in which case it transforms itself into the original nucleus according to the decay scheme

\[
(3) \quad z-1\,^{A}\,^{z}Y \rightarrow \beta^- + \left[ z\,^{A}\,^{z}X \right]^* .
\]

We restrict ourselves to consider only those nuclei \(z\,^{A}\,^{z}X\) which, when
resulting from the radioactive decay (3), are always found in their first excited state.

Then, let us have a beam of 14 MeV neutrons impinging upon a sample which contains the $^{z}X^{\lambda}$ isotope and let us measure both the energy spectrum of the gamma rays emitted in the inelastic scattering reaction (1) (prompt gamma rays) and the energy spectrum of the gamma rays emitted in the radioactive decay (3) (delayed gamma rays).

The prompt spectrum will show a number of peaks due to the $^{z}X^{\lambda}$ nucleus which correspond to the allowed transitions of this nucleus. On the other hand, the delayed spectrum will contain only one peak due to the $^{z}X^{\lambda}$ nucleus produced in the reaction (3): precisely the peak corresponding to the transition of this nucleus from the first excited level to the ground level.

Now, if $N_{1}$ is the number of prompt gamma rays counted in $\tau_{1}$ seconds and associated with the transition of the $^{z}X^{\lambda}$ nucleus from the first excited level to the fundamental level, one has

$$N_{1} = \Phi \frac{d}{\lambda} \rho V \sigma(n,n'\gamma_{1}) \tau_{1} \varepsilon(\gamma_{1})$$

(4)

where:

- $\Phi$ = incident neutron flux ($\text{cm}^{-2} \text{sec}^{-1}$),
- $N'$ = Avogadro's number,
- $\lambda$ = mass number of the target nucleus,
- $\rho$ = density of the sample ($\text{g/cm}^{3}$),
- $V$ = volume of that part of the sample which effectively interacts with the neutron beam ($\text{cm}^{3}$),
- $\sigma(n,n'\gamma_{1})$ = cross-section for the production of the de-excitation gamma ray ($\gamma_{1}$) corresponding to the transition of the $^{z}X^{\lambda}$ nucleus from the first excited level to the ground level in the inelastic scattering of 14 MeV neutrons, (barns),
- $\varepsilon(\gamma_{1})$ = photo-peak efficiency of the NaI(Tl) crystal in the energy range of the gamma-ray $\gamma_{1}$.
At the end of the time interval $T_1$, the sample will contain a number $n$ of radionuclides $Z^{-1}A^A$ given by

$$ n = \Phi \frac{d^r}{A} \rho V \sigma(n,p) \frac{1-e^{-\lambda T_1}}{\lambda} \tag{5} $$

where: $\sigma(n,p) =$ cross-section for the reaction $(n,p)$,

$\lambda =$ disintegration constant of the radio-nuclide $Z^{-1}A^A$ (sec$^{-1}$).

If now one measures the gamma activity of the sample for $T_2$ seconds, the number $N_1$ of the (delayed) gamma rays associated with the transition of the $Z^{-1}A^A$ nucleus from the first excited level to the ground level is expressed by the equation

$$ N_1 = \frac{T_2}{\lambda} \lambda n e^{-\lambda t} dt = \Phi \frac{d^r}{A} \rho V \sigma(n,p) \left( \frac{1-e^{-\lambda T_1}}{\lambda} \right) \left( \frac{1-e^{-\lambda T_2}}{\lambda} \right) \times \varepsilon(\gamma_1). \tag{6} $$

From eqs. (4) and (6) one derives

$$ \frac{\sigma(n,n'\gamma_1)}{\sigma(n,p)} = \frac{N_1}{N_1} \frac{1}{\lambda T_1} \left( 1-e^{-\lambda T_1} \right) \left( 1-e^{-\lambda T_2} \right). \tag{7} $$

3. - EXPERIMENTAL APPARATUS

The measurements have been performed using the 14 MeV neutrons produced by bombarding a tritium target with the deuterons accelerated by means of the 600 keV Cockcroft-Walton of the Istituto di Fisica di Trieste.

In Fig. 1 a block diagram of the experimental apparatus is shown.

The $\alpha$-particle detector was a NE 810 scintillator crystal coupled with a 56 AVP photomultiplier. The $\gamma$-rays were detected by means of a NaI(Tl) crystal coupled with a 6292 Dumont photomultiplier.
An electronic timer (Fig. 2 and Fig. 3) performs the following cycle of operations on the "magnet control unit" (m.c.u.) and on the "multichannel control unit" (M.c.u.) during three successive time intervals $\tau_1$, $\tau_2$ and $\tau_3$.

a) Time interval $\tau_1$. During this interval, the length of which can be varied from 1' to 30', the m.c.u. is operated in such a way as to maintain the deuteron beam on the tritium target, meanwhile the M.c.u. is operated so as to open the first subgroup of 100 channels of a 200 channel-analyzer. Under these conditions, using a fast-slow coincidence circuit, one can measure the energy spectrum of the gamma rays which are in coincidence, within 100 nsec, with the $\alpha$-particles associated with the neutrons which interact with the sample. This spectrum will contain the gamma peaks due to the $(n,n'\gamma)$ reactions. In the experiment, the length of the interval $\tau_1$, was taken equal to $\sigma \times T_{1/2}$, where $T_{1/2}$ is the half life of the radiosotope produced in the $(n,p)$ reaction.

b) Time interval $\tau_2$. During this interval, which can be varied from 1' to 20', the m.c.u. is operated in order to move the deuteron beam away from the tritium target, meanwhile the M.c.u. opens the second subgroup of 100 channels of the multichannel analyzer and excludes the fast-slow coincidence circuit. In these conditions, one measures the energy spectrum of the $\gamma$-activity of the sample, which is due principally to the $(n,p)$ reactions, of Si$^{28}$ with the 14 MeV neutrons, which have taken place during the irradiation time $\tau_1$.

c) Time interval $\tau_3$. During this interval, which is taken equal to $\tau_1 - \tau_2$, the deuteron beam is still moved away from the tritium target and the multichannel analyzer is excluded. Under these conditions, no neutron is produced and the radioactivity induced in the sample during $\tau_1$ has time long enough to decay almost completely.

At the end of the time interval $\tau_3$, the cycle of operations a), b) and c) is repeated.
4. - EXPERIMENTAL RESULTS

The preliminary measurements described in this report concern the determination of the ratio \( \sigma(n,n'y)/\sigma(n,p) \) for the Si\(_{28}^7\) nucleus with reference to the \( \gamma \)-ray \( \gamma \) emitted in the transition of the Si\(_{28}^7\) from the first excited level to the ground level.

The scattering sample used was in the form of a right cylinder and consisted of five elements 4 cm long and 6.3 cm in diameter. Each sample element was made of powder of natural Silicium (92.18% of Si\(_{28}^7\), 4.71% of Si\(_{29}^7\), 3.12% of Si\(_{30}^7\)) contained in a thin-walled perspex cylinder.

The measurements can be divided in the following three groups:

1. measurements of the prompt gamma ray spectra in the range from about 100 keV to about 6200 keV;
2. measurements of the angular distribution of the \( \gamma \)-ray;
3. cyclic measurements of prompt and delayed gamma spectra.

4.1 Measurements of the prompt gamma ray spectrum in the range from 100 keV to 6200 keV.

These measurements have been performed using a 2" × 2" NaI(Tl) crystal in the range from 100 keV to 3200 keV (Fig. 4) and a 3" × 3" NaI(Tl) crystal from 1500 keV to 6200 keV (Fig. 5). A background spectrum is shown in Fig. 6.

By inspection of the spectra of Fig. 4 and Fig. 5, one can recognize a rather pronounced peak, corresponding to the 1778.9 keV transition of Si\(_{28}^7\), and a structure which, in spite of the rather low counting statistics and high background, indicates the presence of other \( \gamma \)-rays. These \( \gamma \)-rays can be attributed to different reactions of the 14 MeV neutrons with Si\(_{28}^7\) or with other materials present in the neighborhood of the \( \gamma \)-detector, such as Na\(_{23}^7\) and I\(_{127}^\) contained in the scintillation crystal itself, Al, Fe, Pb contained in the shields, frames and so on. The position of some of these \( \gamma \)-rays, according with their energy, has been numbered in the Fig. 4, Fig. 5 and Fig.6; the probable reaction and the production cross-section at 90° is indicated in table 1 ([2]).
4.2 Measurements of the angular distribution of the 1778.9 keV gamma-ray ($\gamma_1$).

These measurements have been performed with the 2" x 2" NaI (Tl) crystal and using only one of the sample elements described in par. 4.

The experimental data regarding the angular distribution of the 1778.9 keV gamma-ray are shown in Fig.7. $\theta$ is the angle of observation of the gamma-rays with respect to the direction of the incident neutron beam. $f(\theta)$ represents the counting rate normalized to the counting rate at 90°.

4.3 Cyclic measurements of the prompt spectrum and the delayed spectrum.

The spectrum of the prompt gamma-rays and the spectrum of the delayed gamma-rays measured with the 2"x2" NaI(Tl) crystal are shown in Fig. 8 and Fig. 9 respectively.

The number of counts under the 1778.9 keV $\gamma$-peak is $N_i = 543 \pm 66$ in the prompt spectrum and $N_i = 79 \pm 12$ in the delayed spectrum.

5. - NUMERICAL EVALUATION OF THE $\sigma(n,p'\gamma_1)$

On the basis of Eq. (7) one may write

$$\int_{\theta_1}^{\theta_2} N \frac{d\sigma(n,p'\gamma_1)}{d\Omega} \, d\Omega = \frac{N}{N_i} \left[ \int_{\theta_1}^{\theta_2} \frac{d\sigma(n,p)}{d\Omega} \, d\Omega \right] \frac{1.44 \, T_{\gamma_2}}{\tau_1} \times (1-e^{-\lambda \tau_1})(1-e^{-\lambda \tau_2})$$

where it is $T_{\gamma_2} = 0.693 \frac{\lambda}{\lambda} = 138$ sec.

Assuming for the cross-section $\sigma(n,p)$ the value of 240 mb, as suggested by Cuzzocrea et al. (3), one obtains for $\theta_1 = 50^\circ$ and $\theta_2 = 130^\circ$

$$\int_{\theta_1}^{\theta_2} N \frac{d\sigma(n,p)}{d\Omega} \, d\Omega = 154 \text{ mb.}$$

116
By inserting this value in (8) and using the values \(N_i\) and \(N_i'\) reported in par. 4.3, the left-hand side integral of the expression (8) becomes equal to 67 mb.

Now, by putting

\[
(10) \quad \frac{d\sigma(n,n'\gamma)}{d\Omega} = k f(\theta) \quad \text{mb/sr},
\]

from the expression

\[
(11) \quad \int_{\theta_1}^{\theta_2} \frac{d\sigma(n,n'\gamma)}{d\Omega} \, d\Omega = 2\pi \int_{\theta_1}^{\theta_2} \frac{d\sigma(n,n'\gamma)}{d\Omega} \sin \theta \, d\theta = \pi \sum_{i=1}^{5} k f(\theta_1) \sin \theta_1 \Delta \theta_1 = 67 \text{ mb}
\]

where the values \(f(\theta_1)\) are those represented in Fig. 7, one can derive the value of the normalisation factor \(k\).

The differential cross-section determined in this way is shown in Fig. 10. By making the least-squares fit to the data with the function \(1^4\)

\[
(12) \quad \sigma(\theta) = a + b P_2(\cos \theta) + c P_4(\cos \theta)
\]

the following expression is found

\[
(13) \quad \sigma(\theta) = 10.6 + 10.1 P_2(\cos \theta) + 2.1 P_4(\cos \theta) \quad \text{mb/sr}
\]

which gives for the total cross-section for the production of the 1778.9 keV gamma ray from Si\(^{28}\) the value

\[
(14) \quad \sigma(1778.9 \text{ keV}) = \int_0^{2\pi} 2\pi \sigma(\theta) \sin \theta \, d\theta = 133\pm40 \text{ mb}.
\]

The error is determined principally by the rather low counting statistics.

The value \(14\) agrees with the value of 106\pm16 mb given by Clarke and Cross \(5\) for the total inelastic cross-section for the first excited level of Si\(^{28}\).
Many thanks are due to Prof. G. Poiani for having stimulated the present work and for helpful discussion.

The work was accomplished with the technical help of Mr. S. Jasnić and Mr. G. Kidric.
