R. De Fabbro, G. Matone and L. Satta: A POSSIBLE TEST OF C CONSERVATION IN THE DECAY OF POSITRONIUM.

I. - INTRODUCTION. -

In 1964 the discovery of the $K_L^0 \rightarrow 2\pi$ has pointed out the CP violation in weak interactions. So the interference between the decay amplitude into $2\pi$ of $K_S^0$ and $K_L^0$ (short and long-lived kaon) has been foreseen and experimentally proved. That suggested the idea to search the same interference effect due to a C-violating decay of parapositronium into $3\gamma$.

The positronium system is a bound state of an electron and a positron which, in the ground state, is in $S=0$ ($^1S_0$ - parapositronium) or in $S=1$ ($^3S_1$ - orthopositronium).

However in a microwave magnetic field it is possible to obtain a system which is a quantum mixture of parapositronium and orthopositronium with $S_z = 0$. So the amplitude of the allowed decay $^3S_1 \rightarrow 3\gamma$ and that of the C-violating decay $^1S_0 \rightarrow 3\gamma$ are coherent and interference effects can be observed.

Experimentally Mills and Berko\(^{(1)}\) have put for the branching ratio

$$\mathcal{E} = \frac{\text{rate } ^1S_0 \rightarrow 3\gamma}{\text{rate } ^1S_0 \rightarrow 2\gamma}$$

the upper limit of $2.8 \times 10^{-6}$ with a 68% confidence limit.

They make use of a C-non conserving phenomenological interaction that can cause the decay $^1S_0 \rightarrow 3\gamma$. The simplest nonvanishing form is that suggested by Berends\(^{(2)}\). The parity conserving (C and T non conserving) interaction is given by

$$\mathcal{L}_I = \hbar \left( \frac{1}{2m_e^8} \right) (\bar{\nu}_\mu \gamma_5 \nu_\mu) G_{\mu\nu} F_{\mu\nu} F_{\rho\sigma}$$

\(^{(1)}\)
where
\[ G_{\mu \nu} = \frac{1}{2} \varepsilon_{\mu \nu \rho \sigma} F_{\rho \sigma} \]
\[ F_{\mu \nu} = A_{\mu \nu} - A_{\nu \mu}, \]

Their experiment is designed to separate the C forbidden \( 3\gamma \) decay of \( ^1S_0 \) from the allowed \( 3\gamma \) decay of the \( ^3S_1 \) state by studying the angular distribution of the three photons. Because of Bose statistics, the C non conserving \( ^1S_0 \rightarrow 3\gamma \) rate must vanish for the case of the three photons emerging symmetrically (120°, 120°, 120°) independently of the assumed form of the C non conserving interaction. Therefore the authors measure the ratio of the \( 3\gamma \) rate at the symmetric configuration and at some other set of angles.

We think it is possible to obtain better information about this decay rate observing the interference term between ortho and parapositronium.

II. \( (e^+e^-) \) BOUND STATE AND ANALOGY WITH \( |K^o> \), \( \bar{K}^o> \) SYSTEM.

If we put
\[ \phi_+ = f_e(\uparrow) f_p(\uparrow) \]
\[ \phi = f_e(\uparrow) f_p(\downarrow) \]
\[ \phi_- = f_e(\downarrow) f_p(\downarrow) \]
\[ \bar{\Phi} = f_e(\downarrow) f_p(\uparrow) \]
we can write the triplet and singlet eigenfunction
\[ \psi_{+1} = \phi_+ \]
\[ \psi_o = \frac{1}{2} (\phi + \bar{\Phi}) \]
\[ \psi_{-1} = \phi_- \]
\[ \psi = \frac{1}{\sqrt{2}} (\phi - \bar{\Phi}) \]

As the C parity of positronium system is \((-1)^{L+S}\), its C conserving decay into n-photons, must happen according to \((-1)^{L+S} = (-1)^n\)

where \((-1)^n\) is the C parity of a n photons system: at the lowest order in \( \mathcal{Q} \) we get
\[ ^1S_0 \rightarrow 2\gamma \]
\[ ^3S_1 \rightarrow 3\gamma \]

In the following table we list the symmetry properties under C and CP
of the \( |K^0\rangle \) and positronium system:

\[
\begin{align*}
\text{CP} |K^0\rangle &= |\overline{K}^0\rangle \\
\text{CP} |\overline{K}^0\rangle &= |K^0\rangle \\
|K_S^0\rangle &= \frac{1}{\sqrt{2}} (|K^0\rangle + |\overline{K}^0\rangle) \\
|\Psi_0\rangle &= \frac{1}{\sqrt{2}} (|\Phi\rangle - |\overline{\Phi}\rangle) \\
|K_L^0\rangle &= \frac{1}{\sqrt{2}} (|K^0\rangle - |\overline{K}^0\rangle) \\
|\Psi\rangle &= \frac{1}{\sqrt{2}} (|\Phi\rangle + |\overline{\Phi}\rangle) \\
\text{CP} |K_L^0\rangle &= -|K_L^0\rangle \\
|K_L^0\rangle &\rightarrow 3\pi \\
\text{CP} |K_S^0\rangle &= |K_S^0\rangle \\
|K_S^0\rangle &\rightarrow 2\pi \\
\text{CP} |\Psi_0\rangle &= -|\Psi_0\rangle \\
|\Psi_0\rangle &\rightarrow 3\pi
\end{align*}
\]

Now, it is interesting to point out the analogy of the two systems because we can change from the first to the second column by replacing CP with C, \( |K^0\rangle, |\overline{K}^0\rangle \) with \( |\Phi\rangle, |\overline{\Phi}\rangle \) and weak with electromagnetic (e. m.) interactions.

III. - QUANTUM MIXTURE IN A MICROWAVE MAGNETIC FIELD. -

The perturbing term due to the microwave magnetic field is

\[
(2) \quad V = \mu_o \left( \sigma_{ez} - \sigma_{pz} \right) \frac{H}{2} (e^{-i(\omega t + \psi)} + e^{i(\omega t + \psi)})
\]

where \( \mu_o = \frac{e^2}{2m_e c} = 0.5788 \times 10^{-14} \text{ MeV Gauss}^{-1} \)

\( \sigma_{ez}, \sigma_{pz} \) = Pauli spin operators

\( H \) = microwave magnetic field amplitude

\( \omega, \psi \) = pulsation and phase of H.

General dispersion theory leads to the experimentally confirmed view that the influence of the alternating field will be very small off resonance. We see that in (2) only the term \( e^{-i(\omega t + \psi)} \) can give rise to a resonance phenomenon. The second term produces only dispersion effects which average out during the time of observation (3) and therefore can be dropped.

The matrix element of \( V \) is

\[
\begin{align*}
\langle S_z S_z' | V | S_z S_z' \rangle &= \mu_o H \langle S_z S_z' | \sigma_{ez} - \sigma_{pz} | S_z S_z' \rangle e^{-i(\omega t + \psi)} = \\
&= 2\mu_o H e^{-i(\omega t + \psi)} \delta_{S_z} S_{z'} \left( 1 - \delta_{S_z S_z'} \right)
\end{align*}
\]
4.

The only nonvanishing element

\[ \langle 10 | V | 00 \rangle = D e^{-i(\omega t)} \]

\[ D = 2 \mu \omega \mu H e^{-i\gamma} \]

does not cause a transition from a singlet state to the triplet state \((S_z=0)\). So the superposition principle allows to write the general state of the system in the form

\[ | u \rangle = b_o(t) e^{-\frac{g_1}{2} t} | 10 \rangle + b(t) e^{-\frac{g}{2} t} | 00 \rangle \]

where \(b_o(t)\), \(b(t)\) are the amplitude and \(g = 8 \times 10^9\) sec\(^{-1}\) and \(g_1 = 7,2 \times 10^6\) sec\(^{-1}\) are the total transition probability of the \(| 10 \rangle\) and \(| 00 \rangle\) state respectively.

In the interaction representation the Schrödinger equation for \(| u \rangle\) is

\[ i \frac{d}{dt} | u \rangle = H_{\text{int}} | u \rangle \]

where

\[ H_{\text{int}} = e^{\frac{i}{\hbar} \frac{d}{dt}} \left( -\frac{i}{2} K + V \right) e^{-\frac{i}{\hbar} \frac{d}{dt}} \]

\(H_o\) is the free Hamiltonian

\(K\) is the term responsible of the decay.

Multiplying from left with \(|10\rangle\) and \(|00\rangle\) and remembering the unperturbed Schrödinger equation, we get the two coupled differential equations

\[ b_o = -ib D e^{-pt} \]

\[ b = -ib_o D\dot{x} e^{pt} \]

If \(a_1\) and \(a_2\) are the two roots of the equation

\[ \dot{b} - p\dot{b} + |D|^2 b = 0 \]

and \(v = \omega_o - \omega\) is the difference between the proper pulsation of the system and that of the microwave field, we get

\[ | u \rangle = C_1 \left[ ia_1 e^{i \gamma t} D^{-1} |10\rangle + |00\rangle \right] e^{-\frac{g}{2} \pm a_1 t} + 
\]

\[ + C_2 \left[ ia_2 e^{i \gamma t} D^{-1} |10\rangle + |00\rangle \right] e^{-\frac{g}{2} \pm a_2 t} \]
with $C_1$ and $C_2$ arbitrary constants.

The vector $|u\rangle$ is the sum of two aggregates $|u_1\rangle$ and $|u_2\rangle$ with definite life-times

$$G_1 = g - 2 \text{Re} (a_1) \quad G_2 = g - 2 \text{Re} (a_2)$$

We choose the proper normalization for $|u_1\rangle$ and $|u_2\rangle$ by imposing that $|u_1\rangle$ tends to $|00\rangle$ and $|u_2\rangle$ to $|10\rangle$ when $V$ tends to 0.

Defining $k = |a_1| / |D| = |D| / |a_2|$ and $R^{-2} = 1 + k^2$, we can write

$$|u_1\rangle = \left[ i k e^{i(vt + \theta + \gamma)} |10\rangle + |00\rangle \right] R e^{-(G_1/2 - i \text{Im} a_1)t}$$
$$|u_2\rangle = \left[ i e^{i(vt - \theta + \gamma)} |10\rangle + k |00\rangle \right] R e^{-(G_2/2 - i \text{Im} a_2)t}$$

where $\theta = \theta a_1 = -a_2$ since

$$a_1 a_2 = |a_1| / |a_2| e^{i(\theta a_1 + \theta a_2)} = |D|^2$$

It is immediate to verify that

$$G_1 = \frac{g_1 k^2 + g}{1 + k^2} \quad G_2 = \frac{g_1 + g k^2}{1 + k^2}$$

If $H$ is of the order of 10 Gauss, as can be done with the present techniques, $k^2 \ll 1$ and we have again

$$G_1 \approx g_1 \quad \quad G_2 \approx g_1$$

IV. - INTERFERENCE EFFECTS DUE TO C NONCONSERVATION.

If we believe that a C violating part in the decay amplitude of the singlet state, exists the three photons decay amplitude is composed of two coherent terms, one from singlet and one from triplet, that can interfere.

Let $\mathcal{H}$ be the total Hamiltonian responsible for the decay of $|u\rangle$ and let us calculate the squared matrix elements

$$|\langle 3\mathcal{Y}|\mathcal{H}|u_1\rangle|^2 = R^2 \left\{ k^2 |\langle 3\mathcal{Y}|\mathcal{H}|10\rangle|^2 + |\langle 3\mathcal{Y}|\mathcal{H}|00\rangle|^2 - 2 k \text{Re} |\langle 3\mathcal{Y}|\mathcal{H}|10\rangle x \langle 3\mathcal{Y}|\mathcal{H}|00\rangle| \sin(vt + \theta + \gamma) \right\} e^{-G_1 t}$$
\[ \langle 3\gamma | \mathcal{H} | u_2 \rangle \|^2 = R^2 \left( \langle 3\gamma | \mathcal{H} | 10 \rangle \langle 3\gamma | \mathcal{H} | 00 \rangle \right)^2 - 2k \text{Re} \left[ \langle 3\gamma | \mathcal{H} | 10 \rangle \langle 3\gamma | \mathcal{H} | 00 \rangle \right] \sin(vt - \theta + \varphi) e^{-G_2 t} \]

From the experimental point of view, we must observe the time distribution of the three \( \gamma \) decays with respect to the positronium formation. If \( C \) violating effects are present we have a life-time of about 150 psec. modulated by the interference term.

Care must be taken, however, with the phase \( \psi \). In fact it is a random number which can average out the interference term.

In order to compare the limit that can be put to the branching ratio \( \mathcal{E} \) with the existing one, we assume the lagrangian (1) and describe the \( C \) conserving \( ^3S_1 \rightarrow 3\gamma \) decay with the usual e.m. interaction.

The nonvanishing matrix elements of (1) are those in which the polarization vector of only one photon is perpendicular to the decay plane. The interference term is a function of two independent variables only and it is maximum when the angle between two photons is such that \( \cos \theta_{12} \approx \frac{\pi}{2} \) and \( q_1 \) (the momentum of first photon) is \( \approx 0.5 \) and \( q_1 \) (the momentum of first photon) is \( \approx 0.5 \) and \( \approx 3 \text{ MeV} \).

The oscillating term of \( | u_1 \rangle \) is superposed to an almost flat contribution coming from \( | u_2 \rangle \) and from the \( m = \pm 1 \) states of ortho positronium. Their ratio is \( \mathcal{N} \approx 10 \) h if \( H \approx 10 \) Gauss.

In the hypothesis that we can appreciate experimentally an oscillating amplitude of the order of 10\% (\( \gamma \approx 10^{-1} \)) we can put \( h \approx 10^{-2} \) i.e.

\[ \mathcal{E} = \frac{\text{rate } ^1S_0 \rightarrow 3\gamma}{\text{rate } ^1S_0 \rightarrow 2\gamma} \approx 10^{-10} \]

A rough evaluation of \( \mathcal{E} \) can be obtained as follows(4)

\[ \mathcal{E} \approx \frac{\text{(phase space)}^{3\gamma}}{\text{(phase space)}^{2\gamma}} (q r)^8 \alpha \]

where \( \alpha \) is the fine structure constant and \( (q r)^8 \) account for centrifugal barrier effect, \( q \) is the mean momentum of decay photons and \( r \) is some interaction radius. If we assume \( r \) to be \( \approx 1/\text{me} \), we get \( \mathcal{E} \approx 10^{-8} \).

Concluding, the described method allows the lowering of the present experimental limit on \( C \) violation in \( ^1S_0 \rightarrow 3\gamma \) decay of a factor at least \( 10^4 \).
We would like to thank the theoreticians (G. De Franceschi, A. Grillo, A. Pugliese, F. Strocchi and A. Tenore) for useful suggestions, and E. Di Capua for many stimulating discussions. The constant advices of G. Stoppini is gratefully acknowledged.
