(ricevuto il 24 Gennaio 1983)

Summary. — We calculate relativistic and radiative corrections to the
nonrelativistic (Van Royen-Weiskopf) formula for the leptonic widths of
electron meson ($\pi^0\pi^0$) bound states using $Q^2$-duality. They are determined
by the Schwinger function. This function possesses a simple factorization
which allows us to identify a wave function at the origin and hence to isolate
the genuine radiative correction factor. This latter agrees with the formula
of Karplus and Klein in the appropriate limit. For the quarkonium states
it provides a reliable estimate of QCD radiative corrections. For the $\phi$ and
$\Upsilon$ states these corrections are large. The same is true of the relativistic
corrections.

PACS. 13.20. — Leptonic and semi-leptonic decays of mesons.

1. — Introduction.

In the reconstruction of the potential between a quark and an antiquark,
using inverse-scattering theory (1), one needs, besides the mass locations of the
$q\bar{q}$ bound states, the wave functions at the origin. In the case of the radial

(*) Partially supported by the Deutsche Forschungsgemeinschaft.
excitations of the orthoquarkonium states this means knowledge of the leptonic widths. Although potential models with simple power potentials describe quite satisfactorily the mass spectra of the heavier-quark (q = c, b) bound states \(^{(2)}\), they are less successful in predicting their leptonic widths \(^{(2)}\) with the help of the nonrelativistic (Van Royen-Weiskopf) formula \(^{(2)}\)

\[
\Gamma(V_n \rightarrow e^+e^-) = \frac{16\pi\alpha Q^2 N^2_n}{3(2M)^2} |\varphi_n(0)|^2.
\]

\(V_n(=\psi, \psi', \psi''\ldots; \Upsilon, \Upsilon', \Upsilon''\ldots)\) is a radially excited \(q\bar{q}\) bound state. Its mass will be denoted by \(m_n\) and its coupling to the photon \(m^*_\gamma/n\), in units of the electric charge \(e\). In the same units the charge of the quark is \(Q\), its mass \(M\) and the number of its colours \(N_c(=3)\). \(\varphi_n(0)\) is the wave function of the \(n\)-th bound state evaluated at the origin.

In the case of positronium \(^{(4)}\) eq. (1) is a good approximation, this system being eminently nonrelativistic. Consequently, except perhaps in the masses, relativistic and QCD radiative effects must be more important in the properties of \(q\bar{q}\) bound states than in positronium. These corrections have been extensively discussed recently \(^{(4)}\), but some doubts still persist as to the reliability of their estimates. To these must be added the fact that the inadequacy of the potential model in one area casts doubts on its general validity, however impressive its success in another. The problem, therefore, is not just one of calculating relatively large corrections to the leptonic widths, but more generally of finding a consistent approximation for the description of the structure of quarkonium systems. Even in QED the theory of relativistic bound states is not available in simple form. Secondly, the extrapolation of short-distance–based QCD perturbation theory to long-distance phenomena, such as are relevant to leptonic decays of vector mesons, does not follow unquestionably from knowledge of the QCD Lagrangian. In the past \(^{(4)}\) one tried to come to terms with these problems by assuming that \(q\bar{q}\) bound states were approximately Coulomb-like, so that QED formulae would apply with the appropriate

---

change in the coupling constant. A different approach has been indicated by Durand and Durand (19), who calculated relativistic corrections to the WKB approximation to the wave function at the origin with the help of duality (11,12). The present paper is an extension of the calculation of these authors, to include QCD radiative corrections. We find that, apart from kinematical factors both relativistic and radiative corrections to the leptonic widths of vector-meson bound states are determined by the Schwinger function (14).

There is a simple factorization of this function which allows us to define a wave function at the origin and hence to isolate the purely radiative correction factor. The latter is similar in structure to that of Karplus and Klein (15) and agrees with it rather well numerically. Although we do identify a wave function at the origin, we stress that it is for the purpose of comparison only. Our method is relativistic throughout and, except for the above-mentioned comparison, there is no commitment to potential models. We can and have used our formulae directly to compute the leptonic widths. The results agree rather well with the data except for the $\phi'(3.768)$.

2. – Duality and leptonic decays of vector mesons.

Q$^2$-duality (11,12) is the statement, based on analyticity, that averaged properties of a quark-antiquark bound state are related to those of its constituents. The properties of the constituents which have been related in this way are the charge (11,12) and the mass (14). So far the application has been limited to vector mesons and their quark constituents. Because quarks are supposed to be confined, duality has as a consequence come to be associated with what is supposed to be the dynamics of confined systems. Duality, however, holds also in potential models (15) and with no implication that the potentials are confining. If anything, if duality is pushed to an almost pointwise equality in the way done by Shifman, Vainshtein and Zakharov (19) and implemented by Bell and Bertlmann (19) in potential models, its success becomes inex-

---

applicable in the presence of a confining potential. We wish to consider in such a framework the leptonic decays of neutral vector mesons.

According to duality the energy average of the total cross-section \( \sigma(e^+e^- \rightarrow V_n \rightarrow \text{had}) \) for \( e^+e^- \) annihilation into hadrons is equal to a similar average of the total cross-section \( \sigma(e^+e^- \rightarrow q\bar{q}) \) for \( e^+e^- \) annihilation into the free pair of quark and antiquark constituents of \( V_n \). As a function of the c.m. energy \( \sqrt{s} \) these cross-sections are, respectively,

\[
\frac{\sigma(e^+e^- \rightarrow V_n \rightarrow \text{had}; s)}{f_n} = 16\pi^2 \alpha^2 \frac{m_n^2}{f_n^2} \delta(s - m_n^2),
\]

\[
\frac{\sigma(e^+e^- \rightarrow q\bar{q}; s)}{s} = 4\pi\alpha^2 Q^2 \left( 1 + \frac{2M^2}{s} \right) \left( 1 - \frac{4M^2}{s} \right)^{\frac{1}{3}} \left[ 1 + \frac{4}{3} \alpha_s(s) \ln(\alpha(s)) \right].
\]

\( \alpha \) is the fine-structure constant, \( \alpha_s(s) \) the QCD (strong) coupling constant, \( \nu(s) = (1 - 4M^2/s)^{\frac{1}{2}} \) and \( h(\nu) \) is Schwinger's function \((14)\) defined by

\[
h(\nu) = \frac{1}{\nu} \left\{ \nu \left[ L(1) + L(\nu^2) + 2L \left( \frac{1 - \nu}{1 + \nu} \right) + 2L \left( \frac{1 + \nu}{2} \right) \right] - 2L \left( \frac{1 - \nu}{2} \right) - 4L(\nu) + \ln \frac{1 + \nu}{2} \ln \frac{1 + \nu}{1 - \nu} \right\}
\left\{ \frac{11}{8} \left( \nu + \frac{1}{\nu} \right)^2 + \frac{\nu^3}{2(3 - \nu^2)} - 3 \right\} + \frac{3(5 - 3\nu^2)}{4(3 - \nu^2)} + 6\ln \frac{1 + \nu}{2} - 4\ln \nu \right\}.
\]

\( L(\nu) \) is the Spence function defined by \((14,13)\)

\[
L(\nu) = -\int_0^\nu \frac{dt}{t} \ln(1 - t), \quad 0 < \nu < 1,
\]

\[
L(\nu) = \sum_{n=0}^\infty \frac{\nu^n}{n^2},
\]

\[
L(\nu) + L(1 - \nu) = L(1) - \ln \nu \ln(1 - \nu),
\]

\[
L(1) = \sum_{n=1}^\infty \frac{1}{n^2} = \frac{\pi^2}{6}.
\]

Although \( h(\nu) \) is complicated, its limits for \( \nu \rightarrow 0 \) and \( \nu \rightarrow 1 \) are rather simple. They are

\[
h(\nu) \xrightarrow{\nu \rightarrow 0} \frac{\pi}{2\nu} = \frac{4}{\pi},
\]

\[
h(\nu) \xrightarrow{\nu \rightarrow 1} \frac{3}{4\pi}.
\]

SCHWINGER\(^{14}\) has also given a simple function

\[
\hat{h}(v) = \frac{\pi}{2v} \cdot \frac{3 + v}{4} \left( \frac{\pi}{2} - \frac{3}{4\pi} \right)
\]

which interpolates between these limits.

It is compared with the exact function \(\hat{h}(v)\) in fig. 1. The difference between the two is less than 5% for \(v\) in the interval 0 < \(v\) < 1. The behaviour of \(\hat{h}(v)\) in the nonrelativistic limit (\(v \to 0\)) is compatible with the fact that the probability for establishing a bound state of a particle and an antiparticle in mutual Coulomb (or Coulomb-like) attraction and in relative motion with (nonrelativistic) velocity \(u = 2v\) increases by the factor \(1 + \pi \alpha / 2v\) or \(1 + (\pi / 2v)^{3} \alpha\) in the case of QCD\(^{14,28}\). This means that in the nonrelativistic limit, where potential model descriptions are expected to be valid, one can incorporate \((1 + (\pi / 2v)^{3} \alpha)^{3}\) or \((1 + \pi \alpha / 2v)^{4}\), as the case may be, in the definition of the wave function. It is convenient then to factor \(1 + (\pi / 2v)^{3} \alpha\) out of the entire function.

The factorization, in terms of \(\hat{h}(v)\), is

\[
1 + \frac{4\pi}{3} \hat{h}(v) = \left(1 + \frac{4\pi}{3} \hat{h}_{+}(v)\right) \left[1 - \frac{4\pi}{3} \hat{h}_{-}(v) + \left(\frac{4\pi}{3}\right)^{3} \frac{\hat{h}_{-}(v)\hat{h}_{+}(v)}{1 + (4\pi/3)^{3} \hat{h}_{+}(v)}\right]
\]

with

\[
\begin{align*}
\hat{h}_+(v) &= \frac{\pi}{2v}, \\
\hat{h}_-(v) &= \frac{3 + v}{4} \left( \frac{\pi}{2} - \frac{3}{4\pi} \right).
\end{align*}
\]

Guided by eqs. (6) and (1) we operate an analogous factorization of \( h(v) \) with

\[
\hat{h}_+(v) = h_+(v)
\]
and

\[
\hat{h}_-(v) = h_+(v) - h(v).
\]

Let us now turn to the implementation of duality. Averaging the cross-sections in eqs. (2) and (3) over the energy interval \( m_m - \Delta m/m < \sqrt{\hat{s}} < m_m + \Delta m/m \), one finds

\[
\frac{m_m^2}{f_m^2} = \frac{Q^2}{4\pi^2} \left( 1 + \frac{2M^2}{m_m^2} \right) \left( 1 - \frac{4M^2}{m_m^2} \right) \frac{d\sigma}{dn} \left[ 1 + \frac{4\Delta_4 m_m^2}{3} \hat{h}(v) \right].
\]

The significance of eq. (13) is that, if the mass and charge of the quark are given together with the meson mass spectrum, then the leptonic widths of these mesons are also known. The relativistic formula for the leptonic width in terms of \( f_m \) and the mass \( m_m \) is

\[
\Gamma(N_m \rightarrow e^+e^-) = \frac{4\pi z_4^2 m_m}{f_m^2}.
\]

Substituting for \( f_m \) from eq. (13) into (14) one finds, indeed, that duality relates the leptonic widths to the mass spectrum. For \( N_m = 3 \) one gets

\[
\Gamma(N_m \rightarrow e^+e^-) = \frac{16\pi z_4^2 Q^2}{(2M)^4} \left[ \frac{M^4}{4\pi^2 m_m^2} \right] \frac{d\sigma}{dn} \left[ 1 + \frac{2M^2}{m_m^2} \right] \left( 1 - \frac{4M^2}{m_m^2} \right) \left[ 1 + \frac{4\Delta_4 m_m^2}{3} \hat{h}_-(v) \right] \left[ 1 + \frac{4\Delta_4 m_m^2}{3} \hat{h}_+(v) \right].
\]

Although in the present approach we are not committed to potential models, we wish, nevertheless, for purposes of comparison, to estimate the relativistic and radiative corrections to the leptonic widths computable from such models. To this end we compare eq. (15) with (1) and observe that the WKB approximation for the wave function at the origin in terms of the spectrum of eigen-
values of the Schrödinger equation is

\begin{equation}
|\psi_{n}^{(0)}(0)|_{\text{WKB}}^{2} \approx \frac{M^4}{4\pi^3} m_n \left( 1 - \frac{2M}{m_n} \right) \frac{\text{d}m_n}{\text{d}n}.
\end{equation}

The superscript in $\psi_{n}^{(0)}$ means that the wave function is considered without radiative corrections. Taking into account the argument about the effect of $\lambda_n(\varepsilon)$ in the limit $\varepsilon \to 0$, we identify the terms within square brackets in eq. (15) with the modulus squared of the relativistically corrected wave function at the origin:

\begin{equation}
|\psi_{n}(0)|^2 = |\psi_{n}^{(0)}(0)|_{\text{WKB}}^2 \left( 1 + \frac{2M}{m_n} \right) \left( 1 + \frac{2M}{m_n} \right),
\end{equation}

where

\begin{equation}
|\psi_{n}^{(0)}(0)|_{\text{WKB}}^2 = \left| \psi_{n}^{(0)}(0) \right|_{\text{WKB}} \left( 1 + \frac{4\pi}{3} \lambda_n(\varepsilon) \right).
\end{equation}

Table I. – Relativistic ($r_n$) and radiative ($C_n$) correction factors to the Van Royen-Weiskopf formula for the leptonic widths of the members of the $\psi$ family. Three different values for the quark mass $M$ have been chosen. The leptonic widths in the last column have been calculated from eq. (15) by using the mass formula in eq. (10) to fit the experimental $\psi$ spectrum. For $C_n(\text{KK})$ and $\rho_n$ consult the text.

The remaining factor

\[
C(v; \alpha) = 1 - \frac{4\alpha_s(m_b^2)}{3} h_-(v(m_b^2)) + \frac{4\alpha_s^2}{3} \frac{h_-(v)h_+(v)}{1 - (4\alpha_s/3) h_+(v)}
\]

is then, for this state, the genuine QCD radiative correction factor.

We have computed the relativistic and radiative correction factors \( r_n = \frac{|\psi_n(0)|^2}{|\psi_w(0)|^2} \) and \( C_n(v; \alpha) \), respectively, from eqs. (17) and (18) for the \( \psi \) and \( \Upsilon \) states. The results are shown in tables I and II for three different values of quark masses. We have used for these calculations Schwinger's inter-

</table>

polating function \( \hat{h}(v) \) and the factorization in eq. (1). Also shown in tables I and II is the Karplus-Klein correction factor \( C(v; \alpha)_{KK} = 1 - 16\alpha_s(m_b^2)/3\pi \) with the QCD fine-structure constant. The radiative corrections for the \( \psi \) and \( \Upsilon \) states are thus consistently of the order of 50% and 40%, respectively. No model can, therefore, afford to neglect them. Note the good agreement between \( C_n \) and \( C_n(KK) \) in these tables.

The relativistic corrections, on the other hand, vary a little bit more from state to state and for a fixed state, with the quark mass. They are on the whole larger for the \( \psi \) than for the \( \Upsilon \) states and are comparable to the radiative corrections. Note that \( r_n \) is essentially a product of kinematical factors. It is unity for positronium. A nonrelativistic potential which tries to simulate the effect of \( r_n \) (and \( C_n \)) will have problems with the mass spectrum unless it reckons with a complete breakdown of the WKB approximation for \( \psi_n(0) \). This is difficult to conceive with power law potentials.
3. - Conclusions.

According to eq. (15) leptonic widths of vector mesons are computable if, besides quark charge and mass, the mass spectrum of these mesons is given. Nonrelativistic potential models have been remarkably successful in fitting the spectra of the \( \psi \) and \( \Upsilon \) states. The large relativistic and radiative corrections to the nonrelativistic leptonic widths in tables I and II imply that these models will be equally remarkably unsuccessful in predicting the correct leptonic widths with the help of eqs. (1) and (16). This fact can be surprising only at first sight. The leptonic widths are proportional to the modulus squared of the wave function at the origin. There is no theorem which guarantees that, if a certain potential reproduces a specified spectrum of eigenvalues, then its associated set of eigenfunctions will necessarily be the same as that of the given eigenvalue spectrum (*) . For this to be the case one has to impose that these eigenfunctions satisfy the same boundary conditions. This in turn would say that the potential is unique. This is certainly not the case for the quarkonium states in which completely different potentials are known (**) to reproduce equally well the \( \psi \) and \( \Upsilon \) spectra. The sets of eigenfunctions corresponding to these potentials, that is to say the predictions of the corresponding models for the leptonic widths, are different.

This is where duality becomes useful. It establishes directly a correspondence between the mass spectrum and the leptonic widths which is unique within certain limits. One has now only to check if the correspondence (eq. (13)) is valid. We have done so by fitting the \( \psi \) and \( \Upsilon \) spectra with a mass formula of the form

\[
m_n^2 = m_0^2(1 + bn)^{2+1},
\]

and then used it in eqs. (13) and (14). The values of the parameters \((b, \lambda)\) for the \( \psi \) and \( \Upsilon \) states are, respectively, \((1.67, -0.7)\) and \((0.82, -0.81)\). The predicted leptonic widths are shown in the last columns of tables I and II. Except for the \( \psi' \) \((3.768)\) these widths agree rather well with the data. Gounaris (***) has an argument that, since the \( \psi' \) \((3.685) \) and \( \psi'' \) \((3.768) \) are almost

(*) As an example we note that the parameters of the potentials \( V_1(x) = \frac{1}{3} M \omega^2 x^2 \) and \( V_2(x) = A + B(x/a - a/x)^2, \) \( x > 0, \) can be chosen so that their energy spectra match. The associated eigenfunctions are, however, different; they are proportional, respectively, to the Hermite and Laguerre polynomials.

degenerate, duality should not be applied to them separately but to some weighted average of the two. He gets better agreement with experiment for a linear combination of the two states. It is not necessary for our purposes to enter into these details. The point we wish to make is that the correspondence between the mass spectrum and the leptonic widths established by duality is experimentally valid. We have used this correspondence actually in two ways in this paper:

a) to compute leptonic widths for a given mass spectrum as just discussed,

b) to estimate the relativistic and radiative corrections to the non-relativistic Van Royen-Weiskopf formula.

Does it follow from these applications of duality that short-range forces, and not the long-range confining ones, are dominant in determining the structure of quarkonium states? Poggio and Schnitzer (\textsuperscript{9}) have argued that this is what the validity of the analogy with QED in applying the radiative corrections would imply. Actually duality leads to an even more puzzling paradox, namely that the effect of the quark binding forces can be neglected. Following the work of Shifman, Vainshtein and Zakharov (SVZ) (\textsuperscript{17}), BELL and BERTLMANN (\textsuperscript{18}) have reformulated the problem in this way: under what conditions will the confining potential act as a small perturbation? The problem is still not well understood. However, in the framework of potential models the idea of duality is limited but clear: it is no more than an alternative derivation of the WKB approximation for the wave function at the origin. This latter in no way implies that the binding potential is not effective. In the relativistic theory we conclude, therefore, that duality does not imply that only the short-range part or no binding forces at all are effective. The fact that this principle applies to positronium is, of course, consistent with the usual short-time arguments (\textsuperscript{18,19}). These arguments are seemingly not sufficient for understanding the validity of duality in the case of confined systems.

We think that all this adds up not to a mystery of duality but of confinement. Regarding the question of Bell and Bertlmann then we would speculate that a large part of the confining interaction goes into renormalizing the quark mass down to the mass parameter of that name appearing in all our equations. A choice of this parameter can thus be made such that what remains of the confining interaction can be treated as a small perturbation.

Finally we have compared our result eq. (15) with the definition (17) of the wave function at the origin with the parametrization of Quigg and Rosner (\textsuperscript{8}) of the overall correction to the Van Royen-Weiskopf formula. Their parameter \( \rho \) is related to our \( r_n \) and \( C_n \) by the formula

\[
(m_n/2M)^2 r_n C_n \rho_n = 1.
\]
The values of $q_*$ calculated from eq. (20) are shown also in the tables I and II. They are in the range found by Quigg and Rosner by taking $q$ constant, that is independent of the state $n$.

***

One of us (EE) would like to thank Profs. J. S. Bell and A. Martin for discussions, the former on duality and the latter quarkonium binding potentials. The other (LS) would like to thank the members of National Laboratories of Frascati, where this work was done, for hospitality.

(*) RIASSUNTO (*)

Si calcolano le correzioni relativistiche e radiative alla formula non relativistica (Van Royen-Weiskopf) per le ampiezze leptoniche degli stati legati del mesone vettoriale ($n^8S_1$) usando la dualità $Q^*$. Questo si determinano mediante la funzione di Schwinger. Questa funzione possiede una semplice fattorizzazione che permette d'identificare una funzione d'onda all'origine e quindi di isolare il fattore genuino di correzione radiativa. Questo è in accordo con la formula di Karplus e Klein nel limite appropriato. Per stati del quarkonio fornisce una stima affidabile delle correzioni radiative QCD. Per gli stati di $\psi$ e $\Upsilon$ queste correzioni sono grandi. Lo stesso vale per le correzioni relativistiche.

Релятивистские и радиационные поправки к лептонным шприцам векторных мезонов

Резюме (*). — Мы вычисляем релятивистские и радиационные поправки к нерелятивистской формуле для лептонных шприцов связанных состояний векторных мезонов ($n^8S_1$), используя $Q^*$-дуальность. Эти поправки определяются функцией Швайгера. Эта функция обладает простой факторизацией, которая позволяет идентифицировать волновую функцию в начале и, следовательно, изолировать истинную радиационную поправку. Эта последняя величина согласуется с формулой Карпласа и Клейна в соответствующем пределе. Для состояний кварконумова эта величина обеспечивает надежную оценку радиационных поправок квантовой хромодинамики. Для состояний $\psi$ и $\Upsilon$ эти поправки являются большими. Аналогичные результаты получаются для релятивистских поправок.
